Editorial

Advances in Science, Technology and Engineering Systems Journal (ASTESJ) is an online-only journal dedicated to publishing significant advances covering all aspects of technology relevant to the physical science and engineering communities. The journal regularly publishes articles covering specific topics of interest.

Current Issue features key papers related to multidisciplinary domains involving complex system stemming from numerous disciplines; this is exactly how this journal differs from other interdisciplinary and multidisciplinary engineering journals. This issue contains 111 accepted papers related to computer engineering domain.

Editor-in-chief

Prof. Passerini Kazmersk

ADVANCES IN SCIENCE, TECHNOLOGY AND ENGINEERING SYSTEMS JOURNAL

Volume 6 Issue 2

March-April 2021

CONTENTS

<i>How Ready is Renewable Energy? A Review Paper on Educational Materials and Reports Available for the Teaching of Hydrogen Fuel Cells in Schools</i>	01
Tan Pey Fang, Wan Ramli Wan Daud, Lilia Halim, Mohd Shahbudin Masdar	
<i>A Novel Smart Lock Device with Multistage-Multimode Security Integration</i>	Withdrawn
Durga K Prasad Gudavalli, Swetha Monica Indukuri, V.V.S.Narayana Yirrinki	
<i>Automatic Comprehension and Summarisation of Legal Contracts</i>	19
Sibusiso Kubeka, Abejide Ade-Ibijola	
<i>Curved Pyramidal Metamaterial Absorber: From Theory to an Ultra-Broadband Application in the [0.3 – 30] GHz Frequency Band</i>	29
Zeinab Fneish, Hussam Ayad, Moncef Kadi, Jalal Jomaa, Ghaleb Faour	
<i>Super Resolution Based Underwater Image Enhancement by Illumination Adjustment and Color Correction with Fusion Technique</i>	36
Md. Ashfaul Islam, Maisha Hasnin, Nayeem Iftakhar, Md. Mushfiqur Rahman	
<i>The Analysis of Standard Uncertainty of Six Degree of Freedom (DOF) Robot</i>	43
Auttapoom Lounghongkam, Chana Raksiri	
<i>Green Blocks Made of Recycled Construction Waste using Recycled Wastewater</i>	51
Elgaali Elgaali, Adel Al Wazeer	
<i>Methodology for calculating shock loads on the human foot</i>	56
Valentyn Tsapenko, Mykola Tereschenko, Vadim Shevchenko, Ruslan Ivanenko	
<i>Evaluation the Effects of Climate Change on the Flow of the Arkansas River – United States</i>	65
Elgaali Elgaali, Zeyad Tarawneh	
<i>Fuzzy Analytical Hierarchy Process and Fuzzy Comprehensive Evaluation Method Applied to Assess and Improve Human and Organizational Factors Maturity in Mining Industry</i>	75
Yousra Karim, Abdelghani Cherkaoui	

<i>Design and Implementation of an Ultrasonic Scanner Setup that is Controlled using MATLAB and a Microcontroller</i> Kamel Fahmi Bou-Hamdan	85
<i>Designing and Applying a Moral Turing Test</i> Hyeongjoo Kim, Sunyong Byun	93
<i>Challenges in IoT Technology Adoption into Information System Security Management of Smart Cities: A Review</i> Zarina Din, Dian Indrayani Jambari, Maryati Mohd Yusof, Jamaiah Yahaya	99
<i>Analyzing the Adoption of E-payment Services in Smart Cities using Demographic Analytics: The Case of Dubai</i> Raed Said, Anas Najdawi, Zakariya Chaani	113
<i>A Model-Driven Digital Twin Framework Development for Sulfur Dioxide Conversion Units Simulation</i> Amine Mounaam, Ridouane Oulhiq, Ahmed Souissi, Mohamed Salouhi, Khalid Benjelloun, Ahmed Bichri	122
<i>Application of a Reusability Approach in Simulation of Heritage Buildings Performance, Taif- Saudi Arabia</i> Ali Alzaed	132
<i>Visual Saliency Detection using Seam and Color Cues</i> Sk. Md. Masudul Ahsan, Aminul Islam	139
<i>Multi-Objective Design of Current Conveyor using Optimization Algorithms</i> Abdelaziz Lberni, Malika Alami Marktani, Abdelaziz Ahaitouf, Ali Ahaitouf	154
<i>A Large Empirical Study on Automatically Classifying Software Maintainability Concerns from Issue Summaries</i> Celia Chen, Michael Shoga	161
<i>A Hybrid NMF-AttLSTM Method for Short-term Traffic Flow Prediction</i> Dejun Chen, Congcong Xiong, Li Guo, Ming Zhong	175
<i>The Impact of COVID-19 Pandemic and Commodities Prices on Booking.com Share Price</i> Meng-Chang Jong, Chin-Hong Puah, Ann-Ni Soh	185
<i>Variation of the Air-Fuel Ratio with Inlet Pressure, Temperature and Density</i> Prosper Ndizihwe, Burnet Mkandawire, Venant Kayibanda	190

<i>Designing and Implementation of an Intelligent Energy Management System for Electric Ship power system based on Adaptive Neuro-Fuzzy Inference System (ANFIS)</i>	195
Mohab Gaber, Sayed El-Banna, Mahmoud El-Dabah, Mostafa Hamad	
<i>Exploration of Financial Management Operation of Recognized Student Organizations: A Basis for a Proposed Policy Development</i>	Withdrawn
Rowell Agliones Diaz, Clarizza Lustre De Leon, Edgelly Galvez Vitug,, Lester No Linsangan	
<i>Categorization of RDF Data Management Systems</i>	221
Khadija Alaoui, Mohamed Bahaj	
<i>A Proposed Model of Learning Community in Culinary Community</i>	Withdrawn
Winanti, Ford Lumban Gaol, Meyliana, Harjanto Prabowo	
<i>Forecasting Gold Price in Rupiah using Multivariate Analysis with LSTM and GRU Neural Networks</i>	245
Sebastianus Bara Primananda, Sani Muhamad Isa	
<i>Design Optimization of Open Office Building Form for Thermal Energy Performance using Genetic Algorithm</i>	254
Amany Khalil, Osama Tolba, Sherif Ezzeldin	
<i>Characterization of Gum Arabic in Concrete Mix Design</i>	262
Ali Eltom Hassaballa, Muneeb Yaslam Qabban, Atif Ali Madkhali	
<i>Blockchain Technology-Based Good Distribution Practice Model of Pharmacy Industry in Indonesia</i>	267
Erick Fernando, Meyliana Meyliana, Harco Leslie Hendric Spits Warnars, Edi Abdurachman, Surjandy Surjandy	
<i>Study of Thermo-Physical Characteristics and Drying of Araucaria Wood from the City of El Jadida, Morocco</i>	274
Nora Bouhaddour, Abdelkrim Moufakkir, Sara Belarouf, Abderrahim Samaouali, Hanane Sghiouri El Idrissi, Abdellah Elbouzidi, Salah El Alami	
<i>Numerical Investigation for Failure load and Contact Stress beneath RC Square Footing Resting on Cohesionless Soil</i>	Withdrawn
Mohamed Attia Fouda, Mahmoud El-kateb, Tamer Elkateb, Ayman Khalil	
<i>Factors Affecting Behavioural Intention to Shop in Self-Service Retail Case Study: JD.ID X Mart</i>	285
Tuga Mauritsius, Annisa Safira Braza	
<i>Improved Detection of Advanced Persistent Threats Using an Anomaly Detection Ensemble Approach</i>	295
Adelaiye Oluwasegun Ishaya, Ajibola Aminat, Bisallah Hashim, Abiona Akeem Adekunle	

<i>Fetal Electrocardiogram Extraction using Moth Flame Optimization (MFO)-Based Adaptive Filter</i>	303
Musa Sulaiman Jibia, Abdussamad Umar Jibia	
<i>A Grounded Theory Approach to Digital Transformation in the Postal Sector in Southern Africa</i>	313
Kgabo Mokgohloa, Grace Kanakana-Katumba, Rendani Maladzhi, Sbusiso Xaba	
<i>Investigation of the Impact of Distributed Generation on Power System Protection</i>	324
Ayoade F. Agbetuyi, Owolabi Bango, Ademola Abdulkareem, Ayokunle Awelewa, Tobiloba Somefun, Akinola Olubunmi, Agbetuyi Oluranti	
<i>On the Application of Combine Soft Set with Near Set in Predicting the Lung Cancer Mortality Risk</i>	332

RE

Hydrogen fuel cell teaching programme

Covid-19 online learning

ABSTRACT

Today, the costs of most Renewable Energy (RE) technologies especially hydrogen energy technologies such as fuel cells, are still beyond the means of poorer economies in developing countries. Hence, there is little public awareness and local expertise in RE in these countries and even lesser in hydrogen energy. To solve this problem, it is important to train local manpower in RE, starting with enabling local schoolchildren to learn about RE, especially hydrogen fuel cells. RE provides an alternative, sustainable and clean energy that improves the environment and human life, expands the choice of available energy sources that improves energy security, and reduces consumption of fossil energy in electricity generation and public transportation. Hence it is critical that teaching modules for exposure, acceptance and uptake of RE technologies are developed to suit local conditions. The purpose of this paper is to review recent progress and advances in RE education especially in hydrogen fuel cell. Important features of the modules, educational materials and reports are discussed critically. This paper assesses the literature on RE teaching in schools, especially in hydrogen fuel cells, and discusses the problems faced and the optimal period for cost-effectiveness. A curriculum that integrates literacy and social concepts with science, technology, engineering and mathematics (STEM) concepts could be developed in the future. The literature shows that teaching and learning of fuel cells could be achieved by using the five "Es"; Engagement, Exploration, Explanation, Elaboration and Evaluation, and also by promoting collaboration, team work, communication and design in project based learning activities. Most teaching materials include a project for students to build their own single-cell Proton Exchange Membrane (PEM) fuel cells and electrolyzers, and to produce hydrogen by using solar energy. Appropriate and economic criteria are developed for the design and development of modules for teaching and learning of hydrogen fuel cells, which could be implemented in physical classrooms or on free blended online learning platforms during the COVID-19 pandemic.

1. Introduction

Since the international oil embargo crisis in the 1970s that had threatened energy security of the world, the idea of developing

Renewable Energy (RE) has been widely acknowledged as a measure to stave off a recurrence of the embargo. The increasing acceptance of RE has been primarily attributed to the depletion of fossil fuels especially after the oil embargo crisis. Climate change

^{*}Corresponding Author: Tan Pey Fang, tanpeyfang@gmail.com

<https://dx.doi.org/10.25046/aj060201>

caused by global warming due to carbon emission has been cited as the second most important driver for acceptance of RE. Climate change had manifested itself many times in extreme weather events such as intense heat waves that had hit several European countries such the UK in 2013 [1] and East Asian countries such as South Korea between 2009 and 2012 [2]. Acceptance of RE would reduce the effects of climate change.

Access to energy, energy efficiency and sustainability are the most popular issues in renewable energy (RE) [3]. RE has been found to have a controlling impact on carbon dioxide emissions and therefore climate change [4] and also a positive contribution to a country's economic production [4]-[6]. However, empirical evidence from sub-Saharan African countries have shown that the adoption of RE has not improved their economic power [7]. In addition, RE subsidies in advanced countries have resulted in high RE taxes to finance them that have imposed a heavy burden on consumers [8]. The economic gains and environmental costs of key energy materials such as rare earths are also important issues for and against RE technologies [9]. Furthermore, the high cost of renewable energy needs to be reduced significantly so that RE is no longer beyond the means of poorer economies in developing countries. For example the cost of RE biodiesel could be lowered by using low-cost renewable raw materials such as residual edible oil, inedible oil (*Jatropha curcas* and *Camelina sativa*) and seaweed [10].

The RE economy is a green economy that could provide significant employment in developing and developed countries [11]. In this case, employees and their leaders must be educated in green RE job markets. "Green-collar" workers play a vital role in the development of RE technologies. Students from various level ranging from technical and vocational diplomas in high schools, and science and engineering degree programs in universities could contribute to the sustainable development of the human resources for RE economy [11]. A Chinese study shows that there is a secondary relationship between RE and income [12].

Fuel cells convert chemical energy from molecular bonds in hydrogen and oxygen into electrical energy by an electrochemical reaction. A PEM (Proton Exchange Membrane) fuel cell or PEMFC uses hydrogen gas (H_2) and oxygen gas (O_2) from the air in the reaction and produces electricity, water, and heat. Currently research on PEMFC is focused on developing proton exchange membranes that could operate at high temperature for the High-temperature Proton Exchange Membrane Fuel Cell (HT-PEMFC) [13]. If hydrogen is produced using RE, the green hydrogen so produced could be classified under RE as well.

For Malaysia to stand out in RE technology, there is an urgent need to introduce and integrate RE education into the educational curricula in schools. Although teachers' knowledge content on RE could easily be developed to a satisfactory level, RE education might repeat a major pitfall in science education in Malaysia, which is the inability of science teachers to transfer their knowledge content to the students effectively [14]. Therefore, an essential goal of science or engineering education is to enable these teachers to convey their knowledge to students effectively.

Table 1: Nomenclature Table

No.	Abbreviation	Explanation
1	STEM	Science, Technology, Engineering and Mathematics
2	RE	Renewable Energy
3	PEMFC	Proton Exchange Membrane Fuel Cell
4	HT-PEMFC	High-temperature Proton Exchange Membrane Fuel Cell
5	FC	Fuel Cell
6	HFEP	Hydrogen Fuel Cell Education Program
7	DO	Design Opportunity
8	EiE	Engineering is Elementary
9	STEAM	Science, Technology, Engineering, Arts, and Mathematics
10	FCVs	Fuel Cell Vehicles

This is the first paper in Malaysia to review the readiness of RE education and its educational materials, and available reports on the teaching of hydrogen fuel cell in schools, with the intention of developing teaching modules that could be implemented in the physical classroom. When the COVID-19 pandemic began, there is an urgent need to design and develop modules for teaching and learning hydrogen fuel cells that could be implemented not only in the physical classroom but also conducted online to avoid the pandemic, that is free for all urban and rural children. The authors examine the suitability of these materials to be implemented in the physical classroom and online learning.

The review is intended to provide information, insights and intuitions which would lead the authors and other researchers to develop a cost-effective and economic teaching and learning of hydrogen fuel cells in the country and/or the region. The teaching and learning materials could be transformed into the online learning courses, that is free for everyone. In addition, the blended, interactive online courses with a curriculum created by educators for students and for educators could have the potential of encouraging independent learning, collaboration on projects and hassle-free grading assignments, free for all urban and rural schoolchildren/educators anywhere and at any level, who could learn and stay safe online, avoiding the pandemic.

In this study, we focus upon the recent progress and advances of RE education materials. First, we summarize the objectives of Fuel Cell (FC) education. Then we review the recent features of Hydrogen Fuel Cell Education Program (HFEP) including the teaching method for STEM which includes engineering design, problem solving, collaboration, teamwork, communication and project work. In this part, the science process skills, the design opportunity (DO) element and the design brief which are very important to design and generate solutions to specific problems are

systematically discussed. We also discussed about the recent development in design brief for a project given to the students. Finally, a short conclusion which includes the future perspectives of this RE education materials and challenges in practical application, the cost-effective features and flexibility to be used in blended learning during pandemic crisis are constructively analyzed.

2. Hydrogen Fuel Cell Education Program (HFEP)

2.1. HFEP Objectives

Since the fate of the Earth is in the hands of children, it is crucial and important for them to learn to use RE, and in our case green hydrogen energy and fuel cells at an early age in schools. The main aim of educating schoolchildren on fuel cells and hydrogen energy is to familiarize them with hydrogen energy and fuel cells technology, which would lead to a better, more sustainable, and inhabitable world. The objectives of the HFEP could be summarized as follows

- To accelerate the exposure to fuel cell technology among the schoolchildren
- To encourage the young, who could become future scientists, to perceive fuel cell as an important green energy alternative

2.1.1. Engineering Teaching Method of HFEP

To ensure that the teachers transfer their knowledge content on hydrogen fuel cells effectively to students, a more effective teaching method should be used. One such effective method that we intend to consider is the teaching method for engineering. The teaching method for engineering as suggested by [15], consists of the following fundamental components.

Firstly, the Learning Cycle is summarized as the 5 Es: Engagement, Exploration, Explanation, Elaboration and Evaluation. This is very similar to Bloom's cognitive taxonomy. The first E is Engagement where students are challenged and thought-provoked by reading aloud stories to stimulate imagination and to encourage sharing of ideas. The second E is Exploration where students are encouraged to discover scientific and engineering principle by themselves. This is followed by the third E for Explanation where students explain what happen in different situations and learn from them. The fourth E is Elaborations where students use the knowledge gained to design engineering artefacts. The final E is evaluation where students reflect on their learning curve [15].

Secondly engineering teaching method is contextual learning and problem solving that link their knowledge with the real world by application in problem solving. Thirdly, learning engineering also involves teamwork and collaborative learning in small groups. Fourthly students are also trained in effective communications between team members, clients, and managers. Lastly the engineering teaching method always involve a design project by student that applies all the knowledge that has been learned [15],

The Engineering is Elementary: Engineering and Technology Lessons for Children (EiE) project for American schoolchildren launched in 2003 was a success because it embeds curiosity in the mind of the schoolchildren [16]. EiE not only meet the needs of

children, but also expand the ability of primary educators to teach engineering technology. After the EiE project was launched, the number of schools in the United States that embrace engineering in their curricula increased dramatically.

2.1.2. Science process skill

The amount of knowledge that can be obtained from the teaching of comprehensive Science, Technology, Engineering and Mathematics (STEM) is related to how students perceive the effects of STEM teaching [17]. In Thailand, although a high degree of understanding of scientific ideas and concepts and exceptional presentation of scientific process skills are essential for learning science, most Thai teachers have managed to obtain satisfactory performance for these scientific process skills. These include starting the course by sharing the relevant day-to-day situations of the students, grouping the students into groups, making hypotheses, finding information and planning experiments, conducting experiments, collecting data, explaining and summarizing the results. Then share the results with the class, visit the gallery where experimental conclusions are shown, discuss the class summary, and finally determine the possible sources of errors. To succeed, they start with selective science courses, which have less content, so that they could focus more on encouraging skills related to students' abilities and interests[18].

2.1.3. Important features of the engineering design component of a curriculum

The important features engineering design component include encouraging student creativity, following proven design, open ended problems, search for and use contemporary theories, problem statement and specifications, awareness of alternative solutions, and real-world applications [19].

The features of RE education are flexible and amenable to evaluation by both qualitative and quantitative methods. The DO part is more important than a paper and pencil assessment, while collaborative learning and teamwork are prioritized over individual work. Communication skills are essential in engineering education to prepare future engineers. Students must design and find a solution to a problem. After each session, students share their insights on the learning process and make deep reflections.

Figure 1: Energy related education channel in society [20]

Experimental work is a large component of learning science and engineering. However, learning how to build a fuel cell does not need to start with complicated experimental works. Hurley (2010) believed that anyone with minimum skills and tools will

be able to build high quality fuel cells from readily available materials. Construction of the cells requires a few hand tools only. Apart from setting up a PV solar panel to generate power for the electrolyzer, he also used the “heart” of the fuel cell, namely, the Membrane Electrode Assemblies (MEAs). In 2013, Hurley published a manual that provides five templates for students to build a solar hydrogen fuel cell system and a fuel cell stack. The components include 40-watt solar panels to run the electrolyzers for generating hydrogen fuel, a simple hydrogen storage, and a 6- to 12-watt planar hydrogen FC stack for generating electricity.

A well designed complete curriculum or enrichment programme is able to educate the students to create a sustainable energy practices lifestyle [20]. Energy-aware students could influence their parents to create energy-aware parents. It is going to be a chain reaction, a domino effect, or a snowball effect in the society.

In one study, parents of 16 years old upper secondary rural children, who had just enrolled to study pure science subjects, were found to have acquired positive values towards science and were willing to support and assist their children to improve their achievements in science. These are crucial factors that can help the educationists to plan RE educational intervention involving parents' support in promoting RE learning and careers [21].

2.2. Design Brief

Practical science activities are insufficient in helping students achieve all their learning objectives. Although design task is given to students in groups of two to four, it is better to wait until everyone has their own design ideas before breaking them into groups. Students must be given freedom to carry out their own investigations or create their own designs to Brown's module. This requires a combination of individual learning opportunities [22], which is could be done in two formats where the students must determine the steps required to achieve their goals, or specific steps were outlined for an experiment. After finalizing team designs, students continue with construction, testing, and presentation preparation and project presentations[22].

Another program that emphasizes the importance of engineering design process as the heart of engineering is EiE. By creating and testing lessons that are closely integrated with elementary science topics, EiE aims to strengthen the science program by integrating it with main engineering concepts, broaden their interests, expand children's images of engineering, fostering positive attitudes towards engineers and expectations for the future. Apart from developing curricular materials and resources, the EiE also conducts workshops for educators in the US. Engineers and teachers are involved in the development of a classroom-tested curriculum. The curriculum also integrates literacy and social concepts with science, mathematics, and engineering concepts [16].

2.3. Integration of Engineering Elements in the Modules

Unlike science, the arts played a large role in the history of engineering. Design, the heart of engineering, is more like arts than science. Modern engineering has also benefited much from science and mathematics. Both fields help the engineer to

understand how engineering artefacts behave by simulating mathematically the scientific principles at work in the artefact. Scientific discoveries also provide opportunities for engineers to design novel products that harness the new scientific discoveries to commercialize scientific/engineering products, the arts is used to repackage the product in a much more elegant and attractive manner for the market.

For example, the cell phone is a blend of science, engineering and art. In car industry, science makes the combustion engine work efficiently, while the artistic design of the car complements the masterpiece. In the performing arts, art does not merely refer to acting or singing on the stage but also involves the technology being used at the back-stage.

However, it was only recently that the arts has been integrated into STEM (Science, Technology, Engineering, and Mathematics) to become STEAM (Science, Technology, Engineering, Arts, and Mathematics). An educated person must be able to appreciate art and embrace technology at the same time. The fuel cell is both an engineering and scientific artefact whose invention and design also include the arts.

2.4. Engineering Elements

To integrate engineering elements into the modules, Hershey [23] suggested that students must always be directed by providing them with stimulus after understanding the inventive procedure. The aim of inventing new engineering products should be to improve, enhance, and expand mainstream products to meet social needs. It is important to highlight the importance of merging combinations of elements of many prevailing products to create new products. New opportunities should be recognized by ignoring the rules and using and testing the system. The invention must be "futurized" to ensure the products are up to date. Improve understanding of regulations and use them for innovation. Finally, after completing the invention, you must gather information regarding patent application to protect their rights on the product.

2.5. Economic Features

The experiment or hands-on work need to be simplified by reducing the parts needed so that anyone with minimum skills, tools and materials will be able to produce the product in the teaching manual [24]. A well-designed complete curriculum or programme must be able to educate school children by exposure to RE and FC in an optimal period of time, whose characteristics had been futurized so that it could be updated to suit contemporary circumstances. The teaching module could be implemented in the physical classroom and/or online using blended learning platform that is safe and that eliminates the costs for venue, transportation, etc during pandemic.

3. Hydrogen fuel cells' impacts on securing energy sources and maintaining environmental sustainability

It is important to diversify the types of RE, rather than just relying on specific types. When land and other inputs are transferred from food crops to biodiesel production, the biodiesel industry may lead to competition between fuel and food. [25],

[26]. The biodiesel and oleochemical industries need similar raw materials, which increases their prices. The introduction of biodiesel will directly cause an excessive supply of glycerin, and indirectly lead to a scarcity of oleochemical industry. The glycerin produced must be converted into other useful products. In turn, excessive glycerin will make the price to drop [25].

Malaysia, a major producer of palm oil, produces a lot of wastewater known as the palm oil mill effluent (POME) and empty fruit bunches (EFB) biomass. The adverse impacts of POME towards the environment could be mitigated by reusing the water to overcome water scarcity but reclaiming the water from POME involve cost [27]-[29]. Water treatment by reverse osmosis desalination plants instead of the conventional water treatment plants, incurs higher cost for the integrated/hybrid membrane processes. Usually, a more complicated process is needed for POME treatment such as combinations of membrane filtration unit (microfiltration/ultrafiltration/nanofiltration) with other processes such as adsorption, coagulation, adsorption and ion exchange. [28]. Additionally, natural coagulants could be used with other treatment technologies in integrated/hybrid treatment processes for improved coagulation performance efficiency [29].

Malaysia, a major producer of palm oil, has great potential for H₂ production from POME and EFB biomass by biological treatment but the dark fermentation also produces CO₂ simultaneously. The process is not sustainable until a more reliable and efficient process for separating H₂ from CO₂ is devised and a process to store or reuse the CO₂. The purified H₂ from the gas mixture could be used as a clean source for RE such as in a hydrogen FC [30], [31]. The biogas produced from the further fermentation of POME is already a source of energy around the palm oil mill and could potentially be a major source of RE for Malaysia [31]. Methanol, another fuel for fuel cells, could also be produced from EFB biomass. Methanol FC can be directly applied in mini air vehicles [32].

The success of any bioenergy project is not only determined by technical viability but also by non-technical factors such as authorities, engineers, feedstock producers, and the concerned public [33]. Students have little introduction and experience with hydrogen fuel cells. Hence, students' perception of environmental friendliness of hydrogen fuel cells falls to the eighth, below solar, wind, hydro, wave, natural gas, tidal and geothermal. See Tab. 1 [34].

Table 2: Student perception of environmental friendliness of energy sources (in percent)

Energy Sources	Not Friendly	Little friendly	Less or more friendly	Friendly	Very friendly	Friendliness rank
Natural gas	4.7	10.3	32.5	33.8	18.8	5(52.6)
Solar power	2.6	5.1	8.1	26.9	57.3	1(84.2)
Hydropower	3.8	11.5	24.4	29.9	30.3	3(60.2)
Wind power	4.3	7.3	12.4	21.4	54.7	2(76.1)
Geothermal power	4.3	16.7	33.3	25.6	20.1	7(45.7)
Nuclear power	56.8	16.7	16.7	5.1	4.7	14(9.8)
Coal	47.0	23.1	17.9	5.6	6.4	13(12.0)
Oil	58.5	18.4	9.0	4.7	9.4	12(14.1)
Wave power	9.8	15.4	21.4	26.1	27.4	4(53.5)
Tidal power	5.6	20.1	28.6	24.4	21.4	6(45.8)
Biofuel	20.1	22.2	24.8	25.2	7.7	9(32.9)

Hydrogen fuel Cells	16.2	18.8	26.9	20.5	17.5	8 (38)

Sources:[34]

4. Number of textbooks or references available for teaching fuel cell

For design projects, no manuals, textbooks or workbooks have been provided for students [15], [16] Instead, there are five EiE steps of engineering design process that must be followed: ask, imagine, plan, create, and improve solutions to the given engineering challenges. After the project is accomplished, evaluation is carried out by using a combination of qualitative and quantitative measures.

A Textbook on the introduction of RE technologies in the United States have been published [32]. The one-year science and technology course contain 11 modules. The author associated energy science, fossil fuels and climate change, explores the use and preservation of energy in houses, and establishes energy-efficient energy sources such as solar energy, energy wind energy, hydrogen and fuel cells, biomass energy, biofuels, geothermal energy and hydropower.

Hydrogen fuel cells have attracted widespread attention, and its applications in sustainable transportation have been debated. An introduction to hydrogen is provided, followed by a project for students to build their own fuel cells. The fuel cell kit that includes PEMFC and electrolyzers, could be bought from www.fuelcellstore.com. The student would also need a small solar PV panel to provide the energy to produce the hydrogen. Students are given a fuel cell invention design brief. After students complete their team's mission, each team had three to five minutes to introduce their project. The teams then develops special product handbooks for the inventions. After studying all types of RE, the "RE Final Project" is conducted in 10 to 45 minutes of teaching time or five stages of teaching time. Based on the selected RE source, students developed and tested their design brief. Students not only introduced their projects to the class, but also introduced their projects to school members and local public [32].

The number of textbooks on substitute energy and sustainable energy in the region and the rest of the world is very inadequate. More textbooks need to be written according to local conditions to speed up the adoption of RE in the region. The fundamental physical and technical principles of RE to generate energy, and its impact on the socio-economic and environmental.

5. Country Comparison in Terms of Their Readiness to Embrace FC Technology

After the hydrogen fuel cell is identified as one of the most sustainable, clean and efficient energy sources, the next century is predicted to become the hydrogen era [48], [49]. Hydrogen Fuel Cell Vehicles (FCVs) are expected to have a key influence in energy security and preservation of environmental sustainability.

Table 2: FC Education Materials and Reports Available

Name	Link and Contact	Synopsis	Educational Level
“Build Your Own Fuel Cells”	http://physics.csusb.edu/~tusher/share/Fuel_Cell/build_fuel_cells_05.pdf [35]	Hard / soft convection single slice fuel cell construction. Fuel cell design.	Adults and tenants (not appropriate for children without close supervision of adults familiar with fuel cells) Reached more than 9,600 teachers
“Education And Outreach (By Fuel Cell Technologies Office)”	https://www.energy.gov/sites/prod/files/2014/05/f15/fcto_education_and_outreach.pdf [36]	Professional development for teachers Seven video clips • Developed a two-week study plan. High school student module K-12 project goals • Provide tutoring and training. For the hydrogen and fuel cell future generation of labour market • Together with current K-12 school curriculum, test the developed hydrogen and FCtechnology • Introduction to hydrogen science and technology in the highschoools and primary schools classroom • Run professionals development plan for high school and primary school teachers who will use the course materials x Determine the superiority and efficiency of the course materials • Expand communication chances with new companion • Distribute the curriculum and workshops apparatus to the whole country via teachers’ training and other training programme.	Reached more than 9,600 teachers
“Washington State Fuel Cell Education and Demonstration Program (DOE Hydrogen Program)”	https://www.hydrogen.energy.gov/pdfs/progress04/vii3_vowles.pdf [37]	Develop FCcourses for high schools. Trained 200 junior and senior high school teachers on hydrogen and fuel cells • Provide hydrogen and fuel cell teaching to 18,000 high school students in Washington State. • • Assess the efficiency through an online questionnaire. Proton exchange membrane fuel cell (PEM) demonstration at Central Washington University. • Offer college students with an internship to learn about fuel cells.	Train 200 junior and high school teachers and develop high school curriculum.

An effective transition to a sustainable energy system requires public and private sector funding. Many studies have investigated the Purchase Intention (PI) and buying behaviour of hydrogen FCVs and Alternative Fuel Vehicles (AFCs) in Malaysia. Many researchers have started studying hydrogen FC vehicles, while

others have conducted rigorous reviews of whether attitudes, subjective norms (SN), and control of perceived behaviour are related to customers’ Purchase Intentions (PI) and whether there is a significant association with Purchase behaviour of hydrogen FCVs in Malaysia. These studies are very important for the

decarbonization of the transportation sector in Malaysia and other countries under similar economic conditions[50].

5.1. Malaysia

Of the more than 10,000 schools in Malaysia, about 809 have no power for the whole day, which is particularly common in Sabah and Sarawak. RE sources such as solar panels, wind turbines and micro hydropower plants can meet the electrification needs of rural areas. Take the Penontomon Elementary School (N 4° 52.73'E 116° 15.9') in the Sabah as an example. A solar wind hybrid system was installed to power the guardhouse, tutorial room, computer laboratory and teacher quarters [51]. Before Malaysia can absorb hydrogen fuel cells on a large scale, much work remains to be done.

The biggest benefit of hydrogen is zero emissions, which could help Malaysia achieves the COP15 carbon emission target. Primary energy resources can be used to produce hydrogen in many ways. Hydrogen can be used for transportation, has portable and stationary applications, and could replace fossil fuels [32].

Research and development in hydrogen energy and fuel cells in Malaysia started in Universiti Kebangsaan Malaysia (UKM) in 1995. It was kick-started when a large project of RM 2 million was awarded jointly to UKM and Universiti Teknologi Malaysia (UTM) in 1996 for 5 years from the Intensification of Priority Research (IRPA) fund from Ministry of Science, Technology & Innovation (MOSTI). The same team was granted a much larger project that is 15 fold larger than the first one amounting to RM30 million from the same fund and Ministry in 2002 for 5 years. UKM and UTM team won another large grant of RM7 million from the Ministry of Higher Education (MOHE) in 2013 for 3 years.

It was with this fund that the Fuel Cell Institute (FCI) was established in UKM. The research and development done at FCI are fuel cell system engineering (PEMFC systems), fuel cell electrochemical processes, photoelectrochemical cells, solid oxide fuel cells, direct liquid fuel cells, microbial fuel cells, hydrogen production and solid-state storage and biohydrogen.

Yayasan Sime Darby (Sime Darby Foundation) gave an endowment of RM15 million to establish the UKM-YSD Chair For Sustainable Development: Zero Waste Technology to conduct research and development on hydrogen and biogas production from POME and EFB biomass for power and steam generation, UKM-YSD Chair in collaboration with FCI UKM built a pilot demonstration plant for biohydrogen and biogas production from POME and EFB biomass, CO₂ separation and hydrogen purification and CO₂ storage in algae at a Sime Darby's KKS Tennnamaram, Selangor, Malaysia. A FC buggy is also built to use hydrogen produced by the pilot plant [52].

Recently, Petronas Research Sdn Bhd (PRSB) has granted a large research project of RM 8.25 million to establish the UKM-Petronas Chair of Sustainable Hydrogen Energy in 2019 to conduct research and development on green hydrogen production technology for 5 years. PRSB-UKM is developing new type of electrolyzers at pilot plant scale and plans to build a large FC

buggy and start research and development of photoelectrochemical cells.

The extensive R&D of fuel cells and hydrogen energy in Malaysia over 25 years warrants the introduction of fuel cells and hydrogen energy in the school curriculum in Malaysia. Using a battery and FC based system, a project was carried out in a municipal house in Kapit Village, Sarawak [53]. The same configuration can be used for schools in remote areas in other states of Malaysia. Some Malaysian institutions promoting hydrogen FC education mainly focus on PEMFC technology to provide energy for single-seater vehicles [54]. Following the launch of the fuel FC golf buggy of the FCI UKM and the fuel cell/hybrid electric scooter of Taiwan Chengda National University [36], educators can improve the application of fuel cells by introducing FC programs in their schools through an engineering design teaching module[55].

5.2. Japan

Japanese automakers Honda and Toyota have begun to introduce fuel cell vehicles into their products range [56], [57], [58]. The public showed a positive attitude towards hydrogen infrastructure, but expressed concern about the balance between risk of hazards and benefits brought by FC vehicles [59]. An online study conducted to determine the public's attitude towards installing hydrogen refueling stations near residential areas shows that gender gap need to be reduced through education because men accepted more than women. [60].

5.3. Taiwan

In recent decades, the Taiwan government has actively encouraged FC invention through the national invention system. In [49], vocational education and training (VET) is usually a significant subsystem. Many academic and research institutions in Taiwan have also defined policy tools related to VET[49].

5.4. Africa

In the Eastern Cape Province of South Africa, numerous primary and secondary schools have started to apply hydrogen fuel cells to generate energy reserves. This power supply is used to power devices such as computers, fax machines, and tablets [61].

5.5. US

In Woodbridge, Connecticut, Amity Regional High School uses FC energy to generate 2.2 MW of combined heat and power (CHP). There were fuel cells with small 1.4 MW CHP used in Santa Rita Jail in California [62]. FC teaching not only in schools and universities but extended to national level. The California Fuel Cell Partnership and the Pacific Northwest National Laboratory have conducted hydrogen safety first aid training programs for more than 15 years [63]. The resources developed can be used for advanced general lectures or classroom training, depending on the level of understanding of the demographic of the target group [64].

5.6. European Union (EU)

In 2010, school students in Europe did not learn hydrogen and fuel cells in formal education. There are few textbooks about

hydrogen and fuel cells, and plans are made to introduce hydrogen as a suitable future energy source for transportation sector [65]. In Cologne, a German industrial city, the JIVE and MEHRLIN projects conducted tests in five European countries: Denmark, Germany, the United Kingdom, Latvia and Italy. The project spent €125 million (US\$133 million) and allocated heavy vehicles including 144 hydrogen FC buses and seven large hydrogen fuel gas stations.

The operation of FCVs is relatively quiet and can reduce noise levels in city areas. In public transportation sector around the world, buses are currently operating, and some success stories have proved their continuous improvement in readiness and consistency. However, due to the lack of FCVs hydrogen refueling stations, the infrastructure is still in its infancy.

Besides modelling of the situation in Normandy, France in 2016, some predictions for 2025 were prepared based on the current assessment of the distribution of hydrogen FC vehicles (FCVs) [66]. Cost-benefit analysis shows that the total cost of ownership of hydrogen kangaroos must be halved. High-power vehicles, such as buses and trucks, have played an important role in increasing hydrogen consumption by further expanding the use of FCVs from Normandy to Europe, as well as using cars, buses, and hydrogen-producing trucks other than kangaroos. The two cost components (vehicle cost and fuel cost) involved in deploying an electric FC vehicle (FCEV) can be regarded as a vehicle cost component and a fuel cost component, respectively, and the first component is a more effective than the second component. The cost of introducing hydrogen can be reduced by using a small number of large vehicles to travel on a limited point-to-point route or in a smaller geographic area to promote the widespread use of light hydrogen vehicle [67].

Europeans are aware of the low quality air and noise interference caused by public transportation. Although some cities are starting to use electric vehicles, hydrogen FC buses are still a viable option for most countries that use subsidized diesel buses. Over the past ten years, 84 FC buses operating in 17 cities in 8 European countries have maintained excellent records of flexibility and security. These vehicles can travel up to 300 to 450 kilometers. As a result, there is no need to install infrastructure along the route. If buses and FC cars are mass-produced together, the cost is lower [68].

6. Conclusion and Recommendation

The students must always be guided to provide them with stimulus after exposure to the inventive procedure. In order to invent new engineering products, they should focus on efforts to improve, enhance and expand mainstream products to meet social needs, or to merge useful combinations of prevailing products to create new products and finally to apply for patents. The inventions should also be "futurized" to ensure the products could always be updated.

Soon after the world is tragically affected by the coronavirus COVID-19 pandemic, there is an urgent need to design and develop modules for teaching and learning hydrogen fuel cells that could be implemented not only in the physical classroom but also online learning that is free for all and avoids the pandemic.

After examining the suitability of these materials to be implemented in the physical classroom and online learning, it is recommended that a cost-effective and economic teaching and learning of hydrogen fuel cells in the country and/or the region should be developed. The teaching and learning materials could be transformed into the online learning platform that is free for all.

Implementation of the traditional face-to-face teaching is fraught with problems because of the limited period for related programs and difficulty to get a suitable time to do the intervention. This constraint is due to the difficulty of adjusting schoolchildren learning timetables to accommodate the implementation of the new module. Other obstacles to the implementation are the difficulty of getting the support from the school administrators and the availability of the venue.

In the online setting, the introduction part has to be simple, straight to the point, and usually aided with audio-visual media, which are pre-recorded videos from the instructor or merely the shared videos. Tests and game could be done live during the lessons and the students submit their work online. The submission and grading system will be done online. Besides, these blended, interactive online courses with a curriculum created by educators for students, and even educators for educators have the potential to encourage learning, collaboration on projects and hassle-free grading assignments, free for all urban and sub-urban children anywhere and any level, staying safe online and avoiding pandemic crisis.

context-free grammars

ABSTRACT

Contracts may range from a simple agreement between a tenant and a landlord or a gym contract, or it could be as important as an employment or marital contract. No matter the level of importance, individuals are legally obligated to obey and carry out all clauses in the contract. In this paper, we have identified that the majority of people seldom read through the entire contracts for several reasons such as the size of the contracts i.e. bulky contracts or the inability to fully comprehend a contract. As a solution to the identified problem, this paper presented a software tool that automatically comprehends and summarises legal contracts. We designed context-free grammar (CFG) rules for the recognition of critical clauses found in contracts. These CFG rules were implemented in the software tool. An evaluation of this tool showed that it was able to identify critical clauses in contracts to an accuracy of 79.2%.

1 Introduction

In this section, we present an overview and contributions of the paper. The history of contract laws dates back to prehistoric civilizations which was profoundly influenced by ancient Roman and Greek thoughts [1]–[2]. At the time contract laws were established around a form of action identified as the action of “assumpsit”, which was put into effect in the early 16th century as a solution for the breaches in informal contracts made by word of mouth [3, 4]. As the years have gone by contract laws have evolved and there have been several developments with regards to the type of contracts [5, 6].

With all these new developments of contract laws comes several challenges and unwanted problems, such as the recent discovery that majority of contract receivers fail to thoroughly comprehend bulky contracts which has led to a large number of law cases related to breaches in modern day contracts by contract receivers [7, 8]. Contract receivers are easily exploited by organisations given that they do not have a full understanding of the clauses identified in the contract [9, 10].

In this paper we discussed in great detail a feasible solution to the problems at hand. We mainly focused on developing a web application that is capable of comprehending any legal contract, extracting semantic information as well as generating accurate summaries that includes all the important clauses stated in a contract.

Furthermore, we incorporated an Artificial intelligence concept of natural language processing (NLP) into our proposed solution in order to automatically comprehend and extract critical sections as well as to find patterns from within a contract [11]–[12].

Natural language processing is a phenomenon that has been in existence for close to 50 years and focuses on techniques such as automatic comprehension, summarisation and information extraction. NLP is by far more efficient and will help save time as compared to processing the bulky contracts manually [13].

In order to develop the web application we needed to start with the cleaning out of unnecessary information and white spaces by performing lexical analysis on the contracts, we then outlined a context-free grammar to identify syntactic patterns in the contracts, and finally we had semantic rules that were used to make conclusions on the basis of the identified patterns [14]–[15].

Figure 1 is a graphical representation of the logical flow, that we used to automatically comprehend and summarise a legal contract document. The diagram outlines the different phases a contract will undergo, these phase include pre-processing, document slicing and finally compiling.

The contributions of the paper are as follows. We have:

1. conducted extensive literature reviews on contracts,

*Corresponding Author: Sibusiso Kubeka, University of Johannesburg, Bunting Road Campus, Johannesburg, South Africa, skubeka32@gmail.com

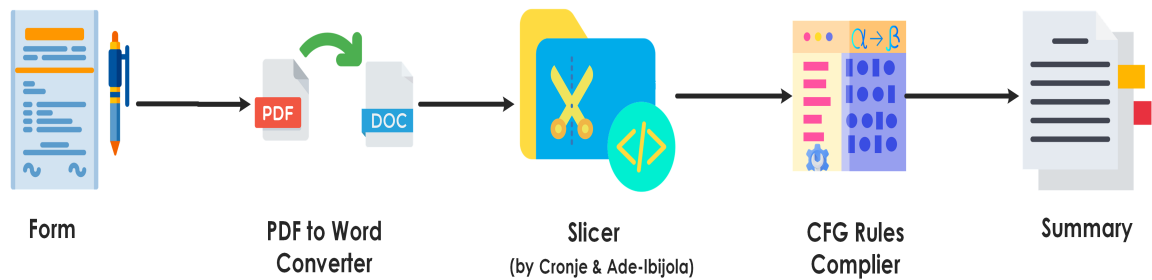

Figure 1: Flow diagram of the comprehension and summarisation process.

2. performed lexical and document slicing of contract documents,
3. identified any hidden implications as well as critical clauses that one should look out for in a contract,
4. formulated context-free grammar rules to help with the identification of patterns within contracts, and
5. implemented the CFG rules into the web application to automatically comprehend and summarise contract documents.

2 Background

In this section, we provided a detailed literature review on contracts, the structure of contracts, different types of contracts that exist, various critical clause found in contracts, information extraction, automatic text comprehension and summarisation, and related work.

2.1 Contracts

A contract can be defined as a promise enforceable by law, it is a legal written agreement that requires the mutual approbation of two or more parties [16, 17]. There are only two roles identified in contracts namely: the person making an offer and the person accepting the proposed offer. If for any reason one of the involved parties fails to adhere to the condition stated in the contract, the other party is entitled to legal reparation [18].

2.2 Structure of Contracts

In this section, we outlined the typical structure of a contract. Contract structures will differ depending on the type of contract.

There are many different types of contracts available and each contract serves a specific purpose [19, 20]. Types of contracts include: General business contracts (Partnership agreements, indemnity agreements, loan agreement and property and equipment lease), Sales-related contracts (Bill of sales, purchase order and security agreement), and lastly Employment contracts (General employment contract, Non-compete agreement and independent contractor agreement).

The structure of a contract typically includes the following categories. Parties to the contract: the details of all involved parties. Recitals: factual information as well as the purpose of the contract. Definitions: explanations of keywords. Conditions precedent: the

state of affairs required. Operative provisions: the rights and obligations of the parties involved. Boilerplate (or Miscellaneous) clauses: important clauses found in a contract. Schedules: the appendix to a formal document. Signatures: distinctive pattern used for identification of parties. The main objective of identifying the structure of a contract is to gain a better understanding in order to be able to recognize the syntax or patterns and create semantic rules to make inferences on identified patterns [21].

2.3 Critical Clauses in Contracts

Within a contract, a clause is defined as a specific section or prerequisite that focuses on an aspect of an agreement. Generally, clauses are used to provide details on aspects such as party duties and roles, rights, regulations, as well as benefits [11, 22, 23]. In this section, we provide a list of critical clauses and important information typically found in legal contract documents. The objective is to identify which information is relevant and should be extracted from an original contract, to create an informative and accurate summary.

Recitals clause

This is a contract clause commonly referred to as the “whereas” clause, it is usually associated with the purpose of a contract. This clause provides the contract receiver with an idea of what the contract is about and why they should sign the contract.

Contract Parties

this section in a contract usually contains information about all parties involved in the agreement. It typically includes the company details, contract receiver information, and any other third party.

Dates

We must be able to extract dates such as “11 July 2020” or “11-07-2020”, as they could be representing important information such as the Commencement or end date of a contract, or it could be a representation of important milestones or conditions that need to be accomplished i.e. “lease period”, “termination dates”, etc.

Period/Duration

This could indicate for instance the duration of the contract or number of hours an individual is required to work in a week. The extraction of keywords such as “10 Hours”, “15 days”, or “three years” is critical and should, therefore, be

included in the summary. Duration and period in contracts are a representation of “working hours”, “inspection period”, and “eviction notice”.

Money/ currency

It is important to extract money and different currency symbols such as “R10”, or ZAR, USD, JYP, etc as these units could represent information such as fines or penalties, salaries, or rent amount. Within a contract money variables are a representation of “Cancellation fees”, “Compensation and benefits”,

Definitions

The summary must include all definition statements found in a contract, these statements normally begin with words such as “is defined as”, “refers to”, “shall mean”, and “means that”.

Conditions

Conditional sentences consist of condition clauses such as “if/ if not”, “when/ when not”, “where”, “as soon as”, “upon the occurrence”, and many other clauses or conditions found in a contract [11].

Amounts

It is important to include non-financial amounts when extracting information for summaries. This could include quantities such as “Three hundred thousand”.

2.4 Information Extraction

Information Extraction (IE) can be defined as the automatic extraction of structured information from unstructured source documents. It takes natural language inputs and can convert them into structured texts using a set of indicated criteria. Information extraction is normally associated with the following sub-tasks: Name Entity Recognition and Linking, Conference Resolution, and Relation Extraction which form part of the segments of NLP tasks like Text Summarisation, Machine Translation, etc. IE technologies are mainly tasked with discovering valuable and relevant information, to construct a significant representation of the original document [24, 25].

There are two types of approaches for automated information extraction using NLP, namely the rule-based approach, and the machine learning-based approach [24, 25]. The machine learning-based approach makes use of machine learning algorithms for text processing based on text features of a certain text [26]. On the other hand, the Rule-based approach employs manually coded rules for text processing. The rule-based approach creates reiterative and refined rules to expand the precision of text processing. The Rule-based approach generally requires more human effort and makes use of several NLP techniques such as tokenization, parts of speech (POS) tagging, phrase structure analysis, and sentence slicing [24]. In this paper, we will make use of context-free grammar (CFG) for syntactic analysis to reduce the number of patterns required in information extraction.

2.5 Automatic Text Comprehension and Summarisation

Automatic text comprehension is a phenomenon that has been in existence since the early 70s and has since become popular in today’s society [27, 28]. Text comprehension is a far more complex task when compared to other computational tasks such as reading or writing (inputting). It is the ability to gain a thorough understanding of a given statement. Understanding a text automatically deduces that one has the ability to form an interconnected and cohesive interpretation of the information found in that particular text. There are several Natural language Processing (NLP) applications that require comprehension of source documents and it is important to note that the majority of those applications comprise of semantic processing of a natural language [28, 29].

Automatic text summarisation is a process related to the construction of a brief and precise version of an original text with the use of a computational software program. The aim is to create summaries that are considerably shorter and contain relevant and important information found within the subsequent document i.e. a contract [30, 31]. Automatic text summarisation can be achieved using two approaches:

Extraction

The extraction-based approach to automatic summarisation focuses on extracting important information based on keywords or key-phrases [32]. The information extracted is not modified nor represented in a new way or form.

Abstraction

The abstraction-based approach, on the other hand, is aimed at using techniques such as paraphrasing in order to provide summaries that are more structured and represent information in a new way, this usually includes information that was not present in the original document. In short, abstractive summaries are semantic representations of the source document.

In this paper, we looked into creating summaries for contract documents using the extraction approach. There is an all-encompassing range of practices that have been recommended for constructing summaries in automatic text summarisation. And it is said that most efficacious practices are based on either the positioning of words/ sentences in a text or on text retrieval. Text retrieval techniques are statistically more fruitful when implemented on source documents for text summarisation.

3 Related Work

From the research that we have conducted it is safe to conclude that very few attempts have been made to automate the comprehension and summarisation of legal documents. There are numerous articles and literature reviews have been published on automatic comprehension and summarisation of source documents using CFGs. Several papers have also been written on the use of natural language processing and machine learning on contracts and legal texts.

FINCHAN

In [29], the author presented an innovative technology that

used a Context-Free Grammar to create a subset of every statement in a given Instant message. This article focused on creating a software application for automatic comprehension and summarisation of financial chats.

LexNLP

In [11], the author proposed a new technology that uses natural language processing as well as machine learning to extract information in legal and regulatory documents. LexNLP is a software designed to enable end-users to turn an unstructured contract into a structured data object. The main aim of LexNLP is to make tasks such as regulation analysis and migration of legal documents a lot easier.

Source Code

Automatic Summarisation of Source Codes in [15], the author proposed a solution that enables software developers to read shorter and accurate source codes to save development time. The solution involves using techniques from automatic text summarisation. The paper states that a combination of summarisation techniques is more effective when summarising source codes.

Semantics in Law

Automatic Extraction of Semantics in Law Documents in [33] present a tool called SALEM, that uses Natural language Processing practices to execute two main tasks, namely classification of law paragraphs in relation to their regulatory substance, and extraction of relevant information in the form of text fragments. The article outlines the architecture of the system as well as a report based on a case study on Italian laws.

Rule Extraction

NLP Approaches for Rule Extraction from Legal Documents by Dragoni presented a software tool that intermixes several Natural Language Processing techniques in order to extract rules found in contracts or legal documents. The paper proposed the combination of linguistic information together with syntax-based extraction of rules from a contract. Furthermore, these techniques will be combined with the logic-based extraction of dependencies.

Summarisation of Legal Texts

In [34], the author proposed a method that automatically summarises legal texts using graph-based summarisation algorithms. Each legal document has its own set of connected graphs, the connected graphs show a cluster which shared the same clause or topic. This method does not require any self-developed linguistic features.

LetSum

An automatic Legal Text Summarising system in [35], the author presented a system that can establish the thematic structure of a legal document and group it into four sections, namely Introduction, context, legal text analysis and lastly the conclusion. From there, the system is able to recognize the relevant text for each section.

3.1 The Gap

People tend to accept or sign contracts without reading through them thoroughly which could result in; Exploitation of contract receivers, the legal cost acquired by contract receivers, etc. Most text summarisation tools are not designated for contract comprehension and summarisation. There has not been any technology developed to provide contract receivers with accurate textual summarisation of critical clauses found in contracts.

In this paper, we were able to identify a gap in that there are no automatic tools that have been developed to help with comprehending and summarising legal contracts. This tool will help the people that struggle with reading bulky contracts by providing them with relevant summaries of contracts.

3.2 Reason for using Context-free Grammars

In this section, we outline the two main reasons for using CFG rules to automatically comprehend contract documents.

Usage of a Document Slicer When developing the tool, we identified that using a document slicer to slice through a contract to recognize relevant sections would increase the accuracy of the findings of the applied CFG rules. For our web application, we made use of an automatic slicer API [36, 37].

Distribution of Grammar Rules The use of CFG rules ensures effortless distribution of grammar rules amongst other researchers and scientists that aim to comprehend or synthesize similar documents. Within the science field, it is critical to have work that can effortlessly be distributed, reusable, or modified by individuals occupied with similar content.

Use of FLAT Formal Languages and Automata Theory (FLAT) refers to a popular feature of Theoretical Computer Science. FLAT is known for having a lot of mathematical theories with very little real-life implementation [38]. The application of FLAT helps with identifying new applications within areas such as computer science education.

3.3 Definition of Terms

Definition 1 (Context-Free Grammar) *Context-free grammar (CFG) is a set of recursive rules utilized to create patterns of a given text. A CFG is formally defined as a 4 tuple, $G = (V, \Sigma, P, S)$ where:*

1. V represents the variables or nonterminal characters (the nonterminal characters indicates the types of clauses found in a sentence)
2. Σ represents a finite set of terminal characters (these are the alphabets of a given language).
3. P represents the production rules.
4. S is the start symbol. The relation $S \in V$ must always hold. [39].

Definition 2 (Lexical analysis) *Lexical analysis also referred to as tokenization or lexing is a computer science process that involves converting a sequence of characters into tokens. A token is usually divided into two sections namely the token name and an attribute value [40, 41]. A lexer is a program that performs lexical analysis and it is often used to find specific patterns such as white spaces, new lines, and digits or letters in any text or document.*

4 Context-free Grammar for Comprehension of Contracts

4.1 Basis

Here we specify the building block for the rules that is presented later in this section. We have three major building blocks namely `n`, `spc`, and lastly `rand_text`. `n` represents any numeric value, `spc` represents tabs and spaces found within a text, `rand_text` represents any random combination of letters that make up words.

4.2 CFG rules

The following are CFG rules for generating the subset of all critical clauses and important information found in contracts. Figure 2 is the syntax tree diagram outlining the structure of contracts. Contracts are grouped into three categories as discussed earlier, namely General business contracts `<gb>`, Sales-related contract `<sr>`, and Employment contracts `<emp>`. A contract `<contr>` includes components such parties to the contract `<pc>` and critical clauses `<cc>`. The production of these components is as follows:

$$\begin{aligned}
 \langle \text{contract} \rangle &\rightarrow \langle \text{gb} \rangle \mid \langle \text{sr} \rangle \mid \langle \text{emp} \rangle & (1) \\
 \langle \text{gb} \rangle &\rightarrow \langle \text{pc} \rangle \langle \text{recital} \rangle \langle \text{CC_comp} \rangle & (2) \\
 &(\langle \text{CC_gb_opt} \rangle \mid \lambda) \\
 \langle \text{sr} \rangle &\rightarrow \langle \text{pc} \rangle \langle \text{recital} \rangle \langle \text{CC_comp} \rangle & (3) \\
 &(\langle \text{CC_sr_opt} \rangle \mid \lambda) \\
 \langle \text{emp} \rangle &\rightarrow \langle \text{pc} \rangle \langle \text{recital} \rangle \langle \text{CC_comp} \rangle & (4) \\
 &(\langle \text{CC_emp_opt} \rangle \mid \lambda) \\
 \langle \text{CC_comp} \rangle &\rightarrow \langle \text{term_date} \rangle \langle \text{comm_date} \rangle \mid & (5) \\
 &\rightarrow \langle \text{comm_date} \rangle \langle \text{term_date} \rangle & (6)
 \end{aligned}$$

All types of contracts contain a section that represents the parties to the contract, hence production Rules 2, 3, and 4 consist of `<pc>`. A parties to the contract section is made up of details about

the company `<com>` and one or more contract receiver `<cr>`.

$$\langle \text{pc} \rangle \rightarrow \langle \text{com} \rangle (\langle \text{cr} \rangle)^+ \quad (7)$$

$$\langle \text{cr} \rangle \rightarrow \langle \text{first_name} \rangle \langle \text{spc} \rangle \langle \text{last_name} \rangle \langle \text{cell_no.} \rangle (\langle \text{email} \rangle \mid \lambda) \quad (8)$$

$$\langle \text{com} \rangle \rightarrow \langle \text{com_name} \rangle \langle \text{com_info} \rangle \quad (9)$$

$$\langle \text{com_info} \rangle \rightarrow x \in (\langle \text{address} \rangle, \langle \text{tel_no} \rangle, \langle \text{fax} \rangle)^3 \ni {}^3P_3 \quad (10)$$

$$\langle \text{address} \rangle \rightarrow \langle \text{area_no.} \rangle \langle \text{spc} \rangle \langle \text{street_name} \rangle \quad (11)$$

$$\rightarrow \langle \text{city} \rangle \langle \text{spc} \rangle \langle \text{postal_code} \rangle \quad (12)$$

$$\langle \text{tel_no} \rangle \rightarrow \langle \text{tel_no.} \rangle \langle \text{n} \rangle \quad (13)$$

Here 3P_3 is a k-permutation of x (i.e. address, tel_no, and fax notices without repetitions).

Recital clauses are found in all contract types. We observed that the word “WHEREAS” is often associated with the recital in a contract, and if a line in the contract start with “WHEREAS” (usually written in capital letters), it often means that the purpose of the contract `<poc>` is to follow.

$$\langle \text{recital} \rangle \rightarrow (\langle \text{rand_text} \rangle \mid \lambda) \langle \text{WHEREAS} \rangle \langle \text{spc} \rangle \langle \text{poc} \rangle \quad (14)$$

$$\langle \text{poc} \rangle \rightarrow (\langle \text{rand_text} \rangle \mid \lambda) \quad (15)$$

The symbols `<CC_gb_opt>` from production Rule 2 is composed of four optional critical clauses: deposit`<deposit>`, lease period `<lease_period>`, rent `<rent>`, and eviction notices `<evic_not>`.

$$\langle \text{CC_gb_opt} \rangle \rightarrow x \in (\langle \text{deposit} \rangle, \langle \text{lease_period} \rangle, \langle \text{rent} \rangle, \langle \text{evic_not} \rangle)^4 \ni {}^4P_4 \quad (16)$$

Here 4P_4 is a k-permutation of x (i.e. deposit, lease period, rent, and eviction notices without repetitions).

The symbols `<CC_sr_opt>` from production Rule 3 is composed of: description of goals `<goal_desc>`, tax/rate `<tax>`, delivery instructions `<del_inst>`, and inspection period `<insp_period>`.

$$\langle \text{CC_sr_opt} \rangle \rightarrow x \in (\langle \text{goal_desc} \rangle, \langle \text{tax} \rangle, \langle \text{del_inst} \rangle, \langle \text{insp_period} \rangle)^4 \ni {}^4P_4 \quad (17)$$

Here 4P_4 is a k-permutation of x (i.e. description of goals, tax, delivery instructions, and inspection periods without repetitions).

The symbols `<CC_emp_opt>` from production Rule 4 is composed of: compensation `<compen>`, benefits `<ben>`, working hours `<hours>`, roles and responsibilities `<roles>`.

$$\langle \text{CC_emp_opt} \rangle \rightarrow x \in (\langle \text{compen} \rangle, \langle \text{ben} \rangle, \langle \text{hours} \rangle, \langle \text{roles} \rangle)^4 \ni {}^4P_4 \quad (18)$$

$$\langle \text{compen} \rangle \rightarrow \langle \text{salary} \rangle \mid \langle \text{wages} \rangle \mid \langle \text{pay} \rangle \mid \langle \text{remuneration} \rangle \mid \langle \text{earnings} \rangle \quad (19)$$

$$\langle \text{roles} \rangle \rightarrow \langle \text{responsibility} \rangle \mid \langle \text{duties} \rangle \quad (20)$$

$$\langle \text{leave} \rangle \rightarrow \langle \text{sick_leave} \rangle \mid \langle \text{annual_leave} \rangle \mid \langle \text{maternity_leave} \rangle \quad (21)$$

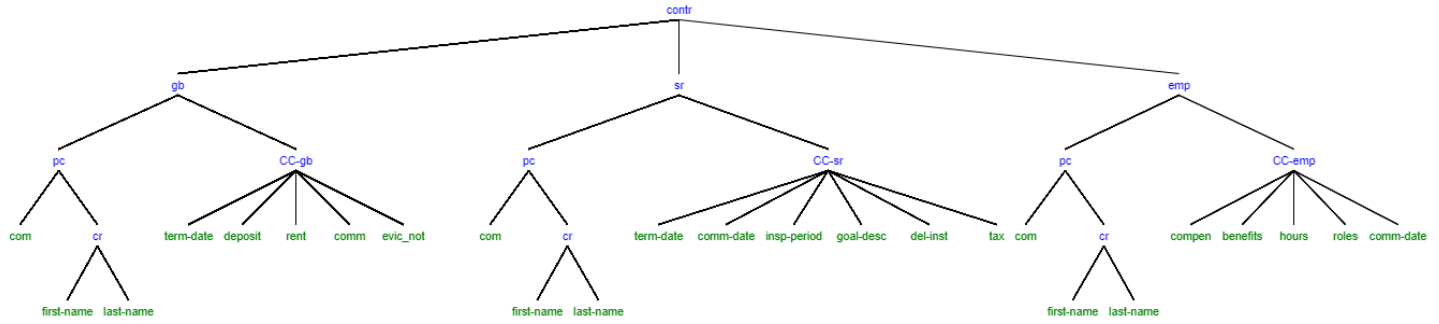

Figure 2: Syntax tree outlining the structure of contracts.

Here 4P_4 is a k-permutation of x (i.e. compensation, benefits, working hours, and roles and responsibilities without repetitions).

We also observed that the words “shall mean”, “is defined as”, “means that” is often associated with definitions found in a contract, and if a line in the contract contains these words it often means a definition is to follow.

$\langle \text{def} \rangle \rightarrow (\langle \text{rand_text} \rangle | \lambda) \text{ (shall mean | is defined as | means that)}$
 $\langle \text{spc} \rangle \langle \text{definition} \rangle$ (22)

$\langle \text{definition} \rangle \rightarrow (\langle \text{rand_text} \rangle | \lambda)$ (23)

Money or Currency:

$\langle \text{cur} \rangle \rightarrow \text{ZAR} | \text{INR} | \text{ZMW} | \text{JPY} |$ (24)

$\rightarrow \text{MUR} | \text{KES} | \text{UGX} | \text{USD} | \text{EUR} |$ (25)

$\rightarrow \text{CNY/RMB} | \text{GBP}$ (26)

Date and Duration:

$\langle \text{date} \rangle \rightarrow \langle \text{day} \rangle \langle \text{spc} \rangle \langle \text{mon} \rangle \langle \text{spc} \rangle \langle \text{year} \rangle$ (27)

$\langle \text{day} \rangle \rightarrow \langle \text{Mon} \rangle | \langle \text{Tue} \rangle | \dots | \langle \text{Sun} \rangle$ (28)

$\langle \text{mon} \rangle \rightarrow \langle \text{Jan} \rangle | \langle \text{Feb} \rangle | \dots | \langle \text{Dec} \rangle$ (29)

$\langle \text{year} \rangle \rightarrow \langle \text{n} \rangle \langle \text{n} \rangle \langle \text{n} \rangle \langle \text{n} \rangle$ (30)

$\langle \text{dur} \rangle \rightarrow \langle \text{year} \rangle | \langle \text{mon} \rangle | \langle \text{days} \rangle$ (31)

Acts and laws: This section includes the important acts and laws that are found in a contract document.

$\langle \text{Act} \rangle \rightarrow \langle \text{Act} \rangle \langle \text{n} \rangle^+ \langle \text{of} \rangle$ (32)

$\rightarrow \langle \text{year} \rangle \langle \text{rand_text} \rangle | \lambda$ (33)

$\langle \text{Act} \rangle \rightarrow (\langle \text{rand_text} \rangle | \lambda)$ (34)

5 Implementation and Results

In this section, we outline the implementation details as well as the results of the proposed tool for automatic comprehension and summarisation of legal contract documents.

5.1 Implementation Details

The Context-Free Grammar rules defined in Section 4 of this paper were executed in a web application using Microsoft’s Visual Studio 2019 as the development environment. We used the .Net framework with Visual Basic as our programming language. Furthermore, we made use of a document slicer API by Cronje and Ade-Ibijola [36].

5.2 Web Application

In section, we present a brief explanation on the sections found in our web application, we will also provide screenshots of the relevant parts of the web application. The web application is made up of three major sections, namely, the home page section, contract summarisation section and the summary section. Figure 3-5 below are the respective screenshots of each of mentioned sections. Table 1 is an example of a summary produced by the tool.

6 Evaluation of Tool

In this section, we presented an in-depth evaluation of our tool based on a performance analysis we had conducted on the tool. We also present the user perception of the tool based on the results gather from a survey we had conducted.

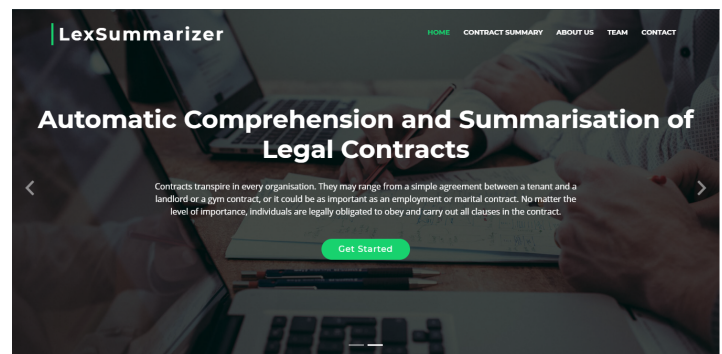

Figure 3: Homepage of the web Application.

Table 1: Example of a summary produced by the tool.

Contract section	Clauses from the tested contract	Information extracted from the contract	Production rule(s)
Acts and Laws	1	The terms and conditions set out herein will constitute the employee's contract with the company. Where a basic condition of employment is not specifically mentioned, the relevant legislation will be applicable (e.g. the Basic Conditions of Employment Act, Act 75 of 1997, the Labour Relations Act, Act 66 of 1995, etc.).	32
	11	The payment of maternity leave will be determined in terms of the provisions of the Unemployment Insurance Act, Act 30 of 1966 read together with the provisions of the Basic Conditions of Employment Act, Act 75 of 1997.	34
	12	in the event of death of the employee's spouse or life partner, parent or adoptive parent, grandparent, child, adopted child, grandchild or sibling.	32-34
	17	The company subscribes to the principle of freedom of association as stipulated in the Constitution of the Republic of South Africa, Act 108 of 1996, and thus the employee may join any organisation/trade union of his/her own choice as regulated in the Labour Relations Act, Act 66 of 1995.	32-34
Leave	8	Leave must be applied for in writing in the form and manner prescribed by the company from time to time, and may only be taken after approval by the company or its delegated authority.	21
	9	An application for sick leave must be supported by a certificate from a registered medical practitioner.	21
Remuneration	4	The employee's total monthly remuneration will be R , payable in arrears on.	19
	5	Benefits	18
	6	The remuneration method in 7.2.1 above will be the normal method of remuneration. Should the employer need to use one of the other options due to circumstances, he/she will inform the employee accordingly, preferably in writing, before the commencement of overtime.	19
	13	The employer may not deduct any monies from the employee's salary unless the employee has agreed thereto in this contract or in writing on each occasion.	19
Working Hours	7	The employer may also by agreement grant two (2) paid working days off in lieu of payment.	17
Termination	3	The employer will be entitled to terminate this contract in terms of the Disciplinary Procedures referred to in paragraph 20 hereof.	5-6
Dates and Duration	16	The appointment under this contract is a full time appointment and the employee shall devote his/her full commitment, energy and attention to the employer's business.	27-31
	10	on a date from which a medical practitioner or a midwife certifies that it is necessary for.	27-31
False positive error	2	During the period of employment within the company the employee will report to (the) and obey instructions given by him/her and any other person duly.	N/A
	15	This limitation of trade is restricted to the nature of the employer's business, products and services.	N/A
	14	The employee will not be liable to the employer for information divulged in terms of legislation or a court order compelling him/her to do so.	N/A

Figure 4: Contract summarisation section of the web Application.

6.1 Accuracy of Tool

The analysis was founded by one perspective, which was, the accuracy in identifying critical clauses in a contract. To measure the accuracy of our tool, we tested it on five different contract documents in which all critical clauses were manually identified before the commencement of the test.

From the first contract were able to identify a total of 22 clauses and our tool was able to identify 17 clauses in the same contract document giving us an accuracy of 77.3%. In the second contract, we manually recognised a total of 14 clauses, and the tool identified 11 critical clauses, which gave us an accuracy percentage of 78.6%. Contract three consisted of five critical clauses and the tool recognized four clauses giving us an accuracy of 80%. The fourth contract we tested consisted of 24 manually recognised clauses and the tool was able to recognise 21 clauses from the same contract. The last contract consisted of seven critical clauses and the tool identified four of those clauses which gave an accuracy of 57.1%.

In total, we were able to manually identify 72 critical clauses from the five tested contracts and our tool was able to identify 57 of these clauses. From these results, we were able to calculate an aggregate accuracy percentage of 79.2%. Given that there are different types of contracts that exist, we can observe the vast difference in the tool's accuracy with every test we conducted.

When conducting our tests on the five different contract documents, we recognised that in some cases the tool presented a few

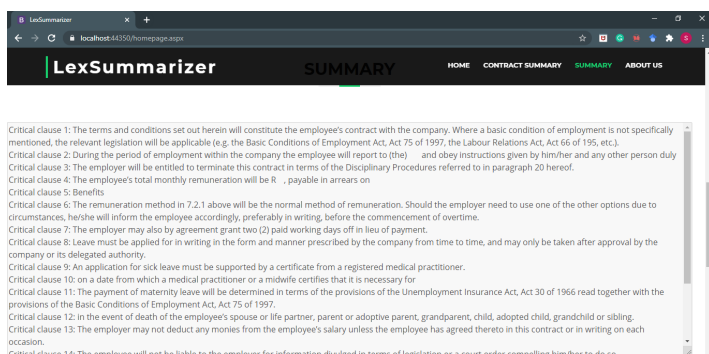

Figure 5: Summary produced by our CFG rules.

statements that did not fall under the critical clause category in the summary, which indicated that our tool produced false-positive errors. To calculate the rate of the false-positive errors we use the formula $\frac{FP}{FP+TN}$, where FP represented the number of false positives and TN was the number of true negatives. The total number of false-positive errors in each of the tested contracts is as follows, contract one had three, contract two had no false-positive errors, contract three consisted of two, contract four had a total of four false-positive errors and lastly contract five consists of two false-positive errors. After calculations, we identified that the tool produced an aggregate false positive rate of 0.13 (13%).

4 and yes
a few time. yes i did
Mostly everything
Just once. Most of the time, but only relevant stuff.
I have signed many software licenses, I have also signed bursary agreements and contracts regarding my studies, contracts for opening bank accounts as well... For the normal contracts I read and understood every clause, but often with software licenses I sign without reading every clause
2, No not every clause
Twice. Yes.
3 times

Figure 6: Number for time participants have received a contract.

6.2 User Perception of Tool

To make our data collection and analysis process less complicated we divided our online survey into two sections, the first section contains questions based on general information and the user's general knowledge and experience on contract documents. The second section included questions that were based on the user's experience of our automatic comprehension and summarisation tool.

Figure 7: The challenges individual have when reading a contract.

From the raw data, we were able to recognize that of the 39 individuals that have read a contract, at least 26 respondents (66.7%) have been exposed to at least 2 contracts in their lives. We were also able to determine that 29 individuals out of the 39 respondents did not understand every clause in the contract documents they have received and read. This gave us a total percentage of 74.3 respondents that struggled to fully comprehend the clauses in a contract document. We were then able to conclude that the introduction of a tool that can automatically comprehend and summarize legal contract documents could provide great assistance to the majority of

individuals who receive contracts but struggle to fully comprehend the terms and clauses found in these contract documents.

Figure 7 outlines that voluminous contracts and the inability to understand legal terms as the main problems individuals generally face when reading a contract. Most of the survey participants agree that tool is useful and relevant.

Figure 8: Usefulness of the tool.

Figure 9: Accuracy of to from participants that tested the tool.

7 Conclusion and Future Work

In this paper we presented a newly formulated approach to automatically comprehend and summarise legal contract documents using formal grammar rules. We started by defining the structure of contracts to gain an in-depth understanding of the different sections found in a contract and their level of importance. We were then able to identify critical clauses that one would normally find in a contract document. From these critical clauses we were able to design CFG rules to outline the syntax of a legal contract document.

Our concept was implemented in a web applications using the .Net framework. When implemented, the web application was able to take any contract document, pre-process the document using the following techniques: PDF-to-Word conversion and lexical analysis. From there the contract is sliced into important sections using a document slicer API. Lastly, the contract is comprehended using our grammar rules and then an accurate summary can be provided.

We were able to perform an in-depth evaluation of our tool based on a performance analysis to measure the accuracy of the tool. The tool was tested on five different contracts and from these tests, we calculated an aggregate accuracy percentage of 79.2%. Furthermore, we identified that the tool produced an aggregate false positive rate

of 0.13 (13%). There was a respectable difference in each of the tests we conducted and we believe these differences were because of the various types of contracts that exist and the way they are structure.

In the near future, we will improve on the comprehension aspect of the presented CFG by designing random forbidden and permitting context grammars.

Broadband Response

ABSTRACT

For its importance nowadays in a wide range of applications such as the anechoic chamber, we introduce a microwave ultra-broadband polarization-independent metamaterial absorber (MA) in the Ultra High Frequency (UHF)/ Super High Frequency (SHF) frequency bands. Through this work, we improved the Relative Absorptive Bandwidth (RAB) of the conventional pyramidal absorber (CPA) by modifying its altitude to a curved shape. As a result, the RAB increased from 25.9 % to 71.82 % with an absorptive level greater than 90% paving the way to an optimized structure for a broader band of absorption. As a second target, we looked for widening the broadband absorption of the CPA in the low-frequency region. To achieve this aim, we introduced two new prototypes. The first with a total thickness of 12.7 cm, consisting of 35 curved resonant layers where numerical simulations show an enhanced design with an absorption band from 0.3 GHz to 30 GHz referring to a RAB of 182%. The second prototype consists of a cell containing different pyramidal absorbers grouped in-plane in a unit cell; such structures operate in complementary bands. This prototype is dedicated to combining these bands of absorption. After that, an enhancement is presented of this latest to reach a well-combined band with a RAB of 128.69%. We used for simulation, testing, and collecting results the High-Frequency Structure Simulator (HFSS) tool.

1. Introduction

This paper is an extension of work originally presented at the 7th Mediterranean Congress of Telecommunications (CMT) conference [1] where we presented an enhanced prototype of a broadband electromagnetic Metamaterial Absorber (MA).

Because of its matched impedance due to the electric and magnetic resonance, the MA is able to omit the reflection by strongly absorbing the incident wave in the dielectric [2]. Based on the latter proposition and in different frequency bands [3-6], other designs of MAs have been introduced. Because its principle is based on resonance, the absorption bandwidth of MAs relies on narrow resonant frequencies. However, broadband absorption is

an important factor in many applications one of them is the anechoic chamber. To overcome this issue, the literature proposes to increase the number of simple resonators with size variation either in longitudinal directions [6] as the pyramidal Absorber (PA) structure by stacking patches resonators or in transverse directions [7]. One of the novelties addressed in this article is a novel prototype that combines these two ways in one model in such a way that the PA structure is used as a part of a unit cell that has different PAs with size variation in the transverse direction.

Because its negligible incident angle dependence [8] and its negligible polarization dependence due to its symmetrical design geometry, the PAs structures achieve a great importance. PA is composed of a periodic array of multilayered patches forming a quadrangular pyramid where these pyramids possess resonant

www.astesj.com

<https://dx.doi.org/10.25046/aj060204>

absorption modes at multi-frequencies in each patch layer. Due to the stacked multi-dimensional patches, we obtain a resonant response on successive multi-frequencies, which the overlapping conduct to a total absorption of the incident wave over a broad band of frequency.

Researches are rarely attempting to resolve the broadband PA below Ultra High Frequency (UHF)/ Super High Frequency (SHF) bands even though many articles have been published [9-12] focusing on the former issue in the microwave, Terahertz (THz), infrared and visible regions.

A metamaterial absorber at this region suffers from a big dimension view of its wavelength dependence. In literature, most of the miniaturized MA that is operative in low frequencies has a narrow band response [13]. Besides, from the industrial point of view, regarding the absorber operation, there exists always a problem of immensity in the frequency band [0.3-1 GHz]. Also, in the latest anechoic chamber, the absorption at low frequency is achieved by two main ways: through heavy ferrite material or by a 1-meter thickness of pyramidal Urethane foam. This specific band gains a high importance because it includes the region of the telecommunication waves. That is why in this work, we design an ultra-broadband PA working in UHF and above regions. We will use a high permittivity dielectric material as a substrate to decrease the dimension of resonators. Moreover, we will enhance the absorption response of a pyramidal design by adding a new factor in optimization. Then the enhanced pyramidal will be used as a unit in two novel prototypes that can achieve an ultra-broadband of absorption.

The first section contains the theoretical model analysis of a conventional PA that is considered as the basic's unit in our broadband design. The study is promoted by simulation results. The second section highlights the effect of using the curved altitude on enhancing the absorption response of the CPA by means of numerical simulations highlighting the improvement of the RAB. After that, two novel prototypes based on PA units are presented aimed to make the absorption response broader in the UHF/SHF band.

All calculations were performed on a High-Performance Cluster (HPC) of 24 cores with a systems memory of 192 GB RAM. Discrete frequency analysis mode was adjusted to make simulation results with very high precision.

2. Conventional Pyramidal Structure

Based on the design equation of the simple patch resonator (1), the resonant absorption frequency f_r is related to the side W of the patch and relative permittivity of the dielectric substrate (ϵ_r) [14]. Then, we can conclude that its response is limited to a narrow band of absorption. For that, stacking multi-dimensional patches is proposed in the literature by PA structures as an efficient way that can widen the band of absorption.

$$f_r = \frac{c}{2W\sqrt{\epsilon_r}} \quad (1)$$

PA design provides broadband absorption. It consists of a periodic array of pyramids with a quadrangular cross shape and a homogeneous metal ground in the bottom, the latter blocking any transmission of the incidence wave ($S_{21} = 0$).

Figure 1: Design of an ultra-broadband PMA, (a) 3-D illustration of the simulation MA, (b) Side view of the PMA unit cell [1].

In this model, the thickness of the metallization layer and the dielectric layers in each patch layer are optimized to be; $t_m = 35 \mu\text{m}$, $t_d = 140 \mu\text{m}$ respectively. The metal used is copper with electric conductivity of $\sigma = 5.8 \times 10^7 \text{ S/m}$. FR4 is used for the dielectric substrate with the relative permittivity of 4.4 and loss tangent equal to 0.02. In this primary model, 20 resonator layers are chosen.

In the simulation, the periodic boundary conditions are assigned along the x and y -directions. A wave port is launched along the z -direction with E field polarized along the y -direction.

RAB defined in (2) is the factor that describes the absorption bandwidth performance of an absorber.

$$RAB = \frac{f_{\max} - f_{\min}}{f_c} \quad (2)$$

where f_c is the central frequency of the absorptive band presented in (3) is given by:

$$f_c = \frac{f_{\max} + f_{\min}}{2} \quad (3)$$

Where f_{\max} and f_{\min} are the upper and lower limits of a frequency range with a specific absorption level, respectively.

The absorption coefficients as a function of frequency from 10 GHz to 28 GHz were shown in Figure 2. There are 20

absorption peaks with an absorbance of approximately above 80%, corresponding to the number of dielectric patches between two neighboring metal interfaces.

Figure 2: The simulation absorption response of the optimized pyramidal structure with dimensions of: $W_{min}=2.975$ mm, $W_{max}=6.3$ mm, $P=6.65$ mm, $t_m=35\mu m$, $t_d=140\mu m$ [1]

As shown in Figure 3, Electric and Magnetic field distributions are plotted at three frequencies (11.5, 17, and 20.45 GHz).

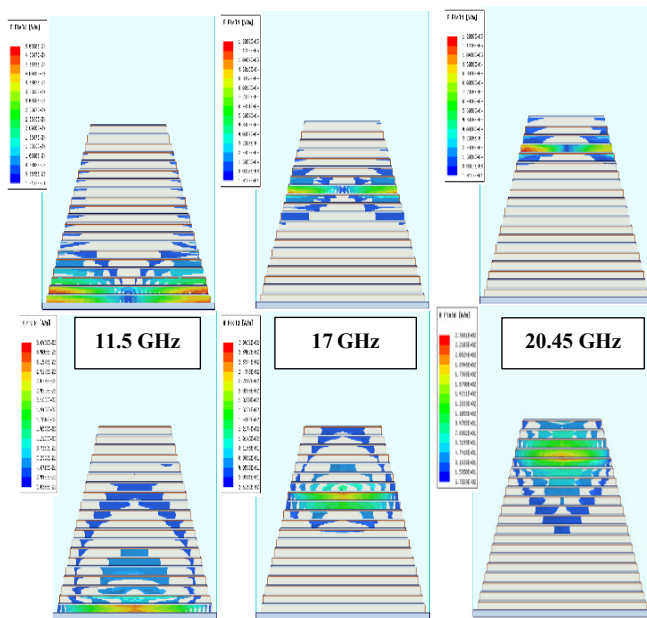

Figure 3: Obtained results of the Magnetic and Electric Magnitude distributions taken at three different resonance frequencies [1]

Results show that each two adjacent metal layers spaced with a dielectric layer can localize an electric and magnetic field at special resonant frequencies. Such resonances lead to zero-reflection by impedance matching to the free space at resonance.

From figure 3, we can observe that, at lower frequencies, the electromagnetic field is localized at the bottom layers of the pyramid. As the frequency is increased, the electromagnetic fields are localized in the upper layers of the pyramid. Since the layers of the pyramid are gradually decreased in width from the bottom to the top, they resonate at different successive frequencies that

ensure an ultra-broadband absorption response. Based on this theoretical study, as the number of layer increases, the absorption window broadens gradually due to additional resonant frequencies

3. Curved Altitude Enhancing Factor

In this section, we include the numerical simulations that show the improvement in the RAB by considering the curved altitude modification on the pyramidal structure. The latter modification adds a new degree of freedom that can improve any pyramidal structure. The unit cell of the pyramidal structure in Figure 1 is considered as a criterion for evaluation of the impact of applying a curved altitude to the pyramidal structure.

Figure 4 shows three different forms of altitudes applied to the same structural parameters. We take the sawtooth altitude (Figure 4 (a)), the linear altitude (Figure 4 (b)), and the curved altitude (Figure 4 (c)).

Figure 4: Diverse altitude design shapes of a Pyramidal structure. (a) Sawtooth Altitude, (b) Linear Altitude, and (c) Curved Altitude [1].

The curve altitude is drawn by a 3-point arc and optimized for the sake of achieving the best outcomes. In Figure 5, we plot the frequency-dependent absorption response for the designs shown in Figure 4.

The simulation results show that the level of absorption in linear and sawtooth altitudes is below 90% at a higher frequency, and it can cover a broad band of absorption but with an oscillator level of absorption (Figure 5 (a) and (b)). This oscillation phenomenon is explained by the need to decrease the difference in dimension between the highest patches on top to ensure nearer resonant frequencies. This result guided us to think about a novel altitude shape. With the curved altitude design, the resonance peaks, at the higher frequency, became nearer to each other and well combined that explains the increase in the RAB. Therefore, the Curved PA reaches 71.82 % RAB with an absorption level above 90% showing a larger absorption compared to that obtained by other altitude forms (see Table 1). This result paves the way to found a new parameter in optimizing such a design.

Table 1: Relative Absorption Bandwidth for different altitude form obtained by simulation results.

	RAB with Absorption level above 80%	RAB with Absorption level above 90%
Sawtooth Altitude	63.3%	25.9%
Linear Altitude	46.3%	33.3%
Curved Altitude	73.4%	71.82%

Figure 5: Absorption response for diverse altitude design shapes: Sawtooth Altitude, Linear Altitude, and Curved Altitude.

4. Absorber Prototypes with an Ultra-Broadband Absorption Spectrum

In this section, we will present two novel structures that can achieve broader absorption results by increasing the number of resonators either in transverse or longitudinal directions as addressed in the subsections below.

As we cited before, our study is directed to get a broad absorption band at lower frequencies. For that, according to the design equation (1) to get a low resonant frequency response, we shall increment the dimension of the considered patch in addition to the relative permittivity of the substrate material.

After the full parametric study, we reached a state in which we can tune the operating frequency to drive the new design to become

absorptive in the UHF band by using dielectric material with $\epsilon_r = 55$ and modifying the fundamental patch to be 72 mm.

4.1. The prototype of Adding Supplementary Patches by Altitude

Due to the role of the conic foam form in the anechoic chamber and for the goal of enlarging the band of absorption, we increased the number of supplementary patches in altitude by 15 using the same stitching method to the pyramid scaled to low frequency consisting of 20 layers as shown in Figure 6 (a). Built up from 35 stacked patches (see Figure 6(b)), the new prototype makes it possible to get a sharp peak at the top; this step can help in decreasing the interface between an electromagnetic wave and the design leading to a higher absorption compared to reflection.

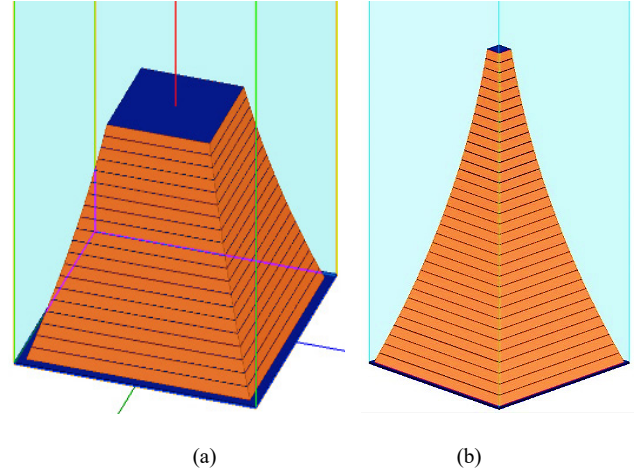

Figure 6: Optimized Pyramidal Design. (a) Prototype of optimized pyramid in UHF Band. (b) Prototype of the Pyramid Absorber after adding 15 patches, the biggest patch is 72 mm in length and the smaller one at the top is 11.7mm [1].

First, we adjust an optimized model of PA with an optimized curved altitude to be operative in the UHF region (Fig.6(a)). Figure 7 displays the spectrum of absorption of such model, it shows an absorptivity exceeding 80% in the frequency band [300-625] MHz. In this structure, we inserted the 15 supplementary layers by height (Fig. 6(b)). Figure 8 aims to verify that the proposed new design reached an ultra-broadband of absorption covering the UHF/SHF frequency regions.

Theoretically, the new design should gives 35 resonant peaks of absorption referring to the basic operation of PA that declare that every patch must resonates in a unique peak of frequency. Luckily, the achieved outcomes crossed over the expectations with an additional factor of absorption at higher frequencies.

In the range [0.3 GHz - 1.92 GHz] of absorption (Phase I), we can explain the absorptive results to the successive resonant absorption modes that occurred at multi-frequencies as expected (fig.9). The reason behind the plots of the electric and magnetic field distributions in Figure 9 is to understand physically the absorption took place in Phase I. In resonant mode, both magnetic and electric resonance exist where they lead to a matching between the absorber impedance and the free space impedance then the wave is absorbed in the dielectric.

Phase II [1.92 GHz- 30 GHz] , with a level greater than 90% (Fig. 8 (b)) the ultra broad-band continues. In this region, the

reason for absorption can be linked to a strong coupling between spaced patches due to the formation of some absorbing modes (see Figure 10). Two main factors clarify the observation: the high permittivity of the considered material that causes a high absorption and the conical geometry with a peaked top that may be responsible for the decrease in the reflection, and To make sure about this result, it has to be experimentally validated.

4.2. The prototype of combining pyramids with complementary bands planar in one unit cell

In this section, we test the efficiency of adding supplementary resonators in the transverse direction to have the broadest absorption response. For that, we apply a novel idea that consists of grouping two kinds of curved and optimized PAs that operate on complementary frequency bands in a one-unit cell. This combined unit cell should also respect the geometrical symmetry that permits to make the model insensitive to the wave polarization as shown in Figure 11.

For that, we adjust two PAs with the same material properties to be absorptive in complementary bands (Figure 12).

As shown in Figure 12, structure 1 operates in the lower band covering [0.29-0.68 GHz] and structure 2 operates in the complementary band covering [0.68-1.48 GHz] with an absorption level greater than 80% in these two structures.

Figure 11: Structure of the combined structure operating in complementary bands

Figure 13: Enhanced Model of the combined structure, considering these geometrical dimensions for structure 3: $W_{3max} = 50.22$ mm; $W_{3min} = 21.06$ mm.

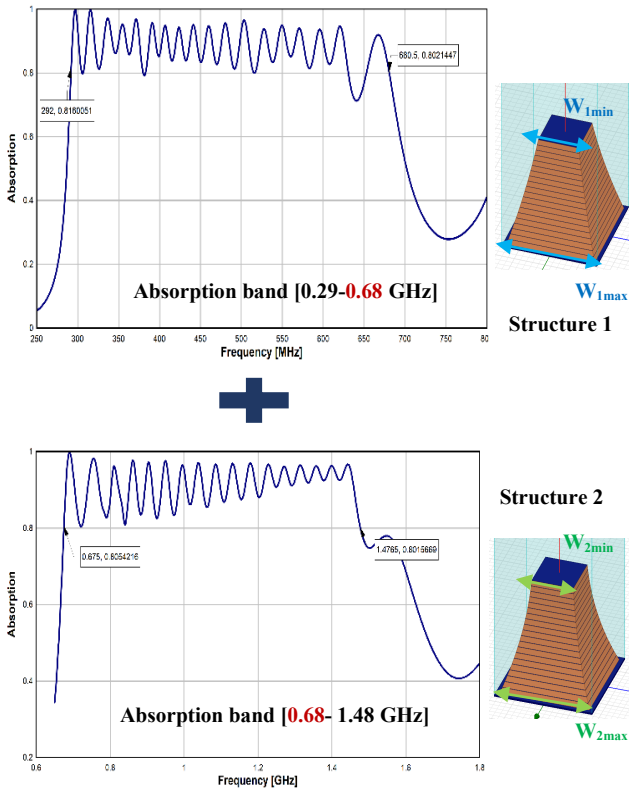

Figure 12: The operating absorption band of structures composing the unit cell with geometrical dimensions: $W_{1max} = 72$ mm; $W_{1min} = 33$ mm; $W_{2max} = 31.5$ mm; $W_{2min} = 14.7$ mm.

This design imposes a geometrical spacing between pyramids with the same dimensions that can degrade the grouping performance of complementary bands. For that, the periodicity between pyramids is taken to be as minimum as possible in such a way to get the pyramids closed to each other and prevent any additional spacing between the same pyramid's dimensions.

To resolve this geometrical disadvantage an enhanced design is presented inserting a third pyramid as shown in Figure 13. The latest pyramid is structured and optimized to operate in a medial band covering [0.42 -0.99 GHz].

Figure 14: Absorption response of the first combined design presented in Figure 11.

From Figure 14, it is shown that the bands are not combined properly, what is particularly striking is the loss of absorption in the lower frequency band due to the increase in the distance between patches of the same size. Increasing the distance between patches will affect the damping coefficient of the structure that directly determines the level of absorption.

The enhanced structure comes to resolve such a problem by adding a third structure operating in a middle band. Results show that the bands are now combined better but a part of the lower band is still below 80% of absorption (Figure 15). By this result, we obtained an absorption band covering [0.41-1.89 GHz] with an absorption level greater than 80%. Such band refers to a RAB of 128.69 %. By this enhanced prototype, the combination is successfully obtained from [0.41 GHz-1.89 GHz]. Such a result shows that there is an extra band of absorption from [1.48 GHz-1.89 GHz]. Figure 10 shows the absorbing modes that cause a strong coupling between spaced patch; such phenomenon represents the cause of the observed extra band of absorption.

Figure 15: The absorption level of the design presented in Figure 13.

5. Conclusion

Due to the remarkable characteristics of the pyramidal design, we covered a full theoretical study in this paper. We take this structure as a basic model in our study by different geometrical shapes. The curved altitude is found as an enhancing factor where the relative absorption bandwidth increase from 63.3 % to 73.4 % with an absorption level greater than 80 %. Added to these results, we presented two novel prototypes based on the PA that can achieve a broader absorption response.

Generally, the broadband objective can be achieved by increasing the number of resonators with size variation either in transverse or longitudinal directions. That is was applied in this article based on pyramidal units instead of simple patches where they were combined in-plane and in altitude. Each idea was showed its efficiency in broadening the absorption band. We reached a RAB of 182.83 % by applying the curved pyramid of 35 layers and 128.69 % when applying the transverse combining method. The novelty in the ways of patches structuring applied in this article, admits to a RAB values unreachable in many broadband absorber essays in literature.

For achieving important results from the considered prototypes, there is a need for experimental testing after fabrication.

Super Resolution

ABSTRACT

In underwater photographs are look like low-quality images, the main reason is behind that due to attenuation of the propagated light, absorption and scattering effect. The absorption significantly reduces the light energy, while the dispersion causes changes in the light propagation path. They result in foggy appearance and degradation of contrast, causing misty distant objects. So, for getting the most effective result from that type of image, there must be an enhancement technique that has to be applied. We propose an efficient technique to enhance the images captured underwater by applying a fusion-based technique using super-resolution. For enhancing images, we have followed two steps. The first one illumination adjustment and another one is color correction. Then fusion technique is applied to the resultant image from illumination adjustment and color correction as two inputs and combined them with their maximum coefficient value and received output from there. After that, on the fused output image, we used the Super-Resolution method. In the Super-resolution procedure, low resolution and high-resolution images are used then a bi-cubic interpolation algorithm and finally, VDSR (very-deep super-resolution) neural network has been used to get the most effective result from an obscure underwater image. For getting the most effective result from an obscure image, a new high-quality and efficient image enhancement method has been proposed in this paper.

1. Introduction

Under water photographs have been commonly used in marine life under water studies in recent years. Underwater photography has jointly been a primary objective of concern in various technology and science branches, such as scrutiny of underwater infrastructures and cables, object tracking, underwater vessel control, marine biology review, and archeology [1]. Underwater images are primarily depicted by their poor visibility as a result of

the light is exponentially weakened within the underwater atmosphere [2]. The entities at a distance more than ten meters are almost undetectable in common seawater pictures; the colors get faded [1]. Water absorbs light, reducing light rays' energy, resulting in image under-exposure [3]. The reasoning for the color cast is that there is a differing absorption rate for the varying wavelengths of light [4]. The key challenges, including color casting, fuzz, and under-exposure, can be faced by underwater imaging processing. It ought to be handled to recoup the comparatively true color and normal aberrance to make the collected photographs more appropriate for observation [5]. This can be done by either image restoration or image enhancement

^{*}Corresponding Author Name: Md. Ashfaul Islam, Bangladesh Army University of Engineering and Technology (BAUET), Natore, 6431, Bangladesh, +8801723859090 & niloy064@gmail.com

procedures [6]. For enhancing the underwater images, it is the most important part to develop some algorithms like illumination adjust, color correction, fusion technique & restoration process to get the most effective result from a non-uniform image. We do super-resolution by revising the arbitrary visual appearance of the image by generating higher images from low-resolution pictures [4].

2. Previous Research Work

To solve the obscurity of a photograph shot in an underwater setting, a lot of work has already been completed. Three big problems occur in underwater photography, including color casting, under-exposure, and fuzz. In [1], the author proposes a new method formed by two components: correction of color and illumination modification. In order to overcome the color cast, they used an appropriate color enhancement technique and then followed the Retinex model to make the illumination adjustment by successively applying a gamma correction on and removing the illumination map. In order to eliminate the haze in underwater photographs that do not require advanced hardware or information about the underwater environments or scene composition. Their approach relies on the fusion of multiple inputs, but by contrast correcting and enhancing the sharpness of a white-balanced version of a single native input image, they derive the two inputs to merge [7]. Eliminating the color cast by white balancing to create a realistic appearance of the underwater pictures, and the multi-scale application of the method of fusion results in an artifact-free blending. To dramatically upgrade the color of underwater images, the author used contrast stretching and HSI color space [8]. Again, author of [1] implemented a fusion approach that used the global min-max windowing strategy for maximizing contrast. In [6], the author order to distinguish less contrast, researchers have used histogram expanding technique and CLAHE for color correction and contrast enhancement techniques. The unsupervised color correction method is applied by the author of [9] to increase the resolution of a low-quality picture.

For increasing the accuracy of the images of underwater, we are doing this because it has been used in many research sectors in recent years. By reviewing some previous works, we can see that they have separately worked with different techniques, but in our work, we have combined the different techniques - illumination adjustment and color correction with fusion technique and super resolution for the better output than others.

In our article, we have worked on the various procedures for enhancing an underwater image. There we have worked on illumination adjustment, color correction first to enhance the image. Then the fusion technique is applied to the modified image we get by balancing the illumination and correcting the color, and finally, we have used the super-resolution process on fused output image to get the best effective result from the input image.

3. Proposed Architecture

Basically, there are four sections in the proposed architecture. In the first section, we have described the illumination adjustment technique. In section two we have described the color correction part. In section three, the fusion technique has been described and finally, we have briefly described the super-resolution process in section four.

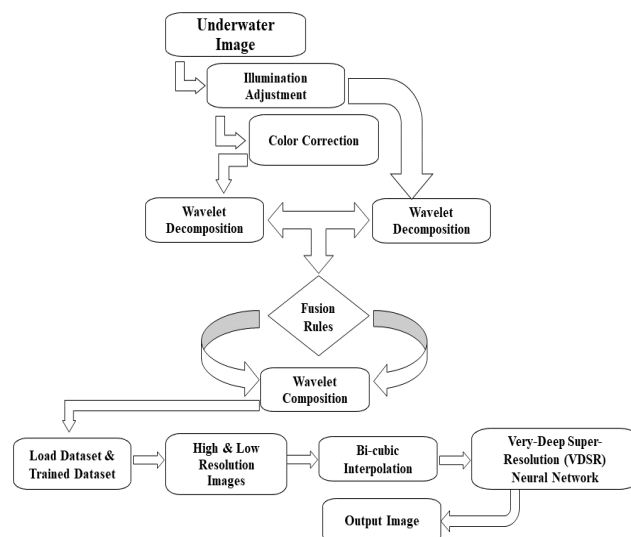

Figure 1: Proposed System Architecture.

3.1. Illumination Adjustment

Illumination adjustment basically is to falling the light on objects and making them visible as they are illuminated, it happens for scaling up the light in the water. Explaining $M \times N$ underwater images illumination of a by illuminant is possible, etc. [6]

This is our input image 1 we are working on.

(1)

In the illumination adjustment process for removing illumination, firstly there we have used the grayscale algorithm to convert the original image into a grayscale image.

(2)

We then used the Adaptive Histogram Equalization on the grayscale image to control the local contrast of the pixels from the adjoining area, essentially it is used to increase the image contrast.

(3)

In order to fix the image luminance, we subtracted the background from the Adaptive Histogram image and applied the gamma correction algorithm to the image. After that we used median filter on the image, it is generally used for removing noise (unwanted pixel) from the image. The total progression, from background subtracting to image filtering, is repeated twice (three times in total) to change back to an image's RGB color space.

(4)

After that, the three results we got from filtered images are correlated with the processing from the illumination grayscale image of the illumination attuned RGB image.

(5)

Here we have shown the same procedure for a another input image for better understanding.

3.2. Color Correction

In the procedure of color correction, the illumination adjusted images' output is used as the input image of color correction.

(1)

Images are influenced by low contrast because of dispersion in the underwater environment. Firstly, the RGB space of the illumination adjusted image is converted into HSV (Hue Saturation Value).

(2)

Then HSV is prepared to point up the maximum visible portion of the output we have with max luminance. It is a useful technique that is used to increase the contrast of an image for balancing image intensity after Histogram Equalization is used on the processed image.

(3)

However, sometimes demolitions disclose parts and present a nonuniform result. For this reason, here we use Adaptive Histogram Equalization on the Histogram Equalized image of the input image of the color enrichment. Adaptive Histogram is the up-gradation process of Histogram Equalization.

(4)

Adaptive Histogram Equalization operates by contemplating only a small component and produces a contrast enhancement of

this part based on the surrounding CDF. Histogram Equalization technique is performed to measure the intensity of the individual structure of the image, this. and especially changes each RGB channels color.

3.3. Fusion Procedure

Combination procedure fundamentally may be a method of combining apocope data from two or more images into a single image, the yield image will represent more data than the input image. Within the Combination method, Wavelet Changes are fundamentally the developments of the plausibility of Tall pass sifting. The way towards applying the Discrete Wavelet Transform (DWT) can be talked to as a bank of channels. At respectively degree of decay, the flag is separated into tall recurrence and low-

frequency elements, and the low-frequency portion can be moreover decayed till we get the perfect determination. The Wavelet change is deliberate to urge awesome recurrence determination for low-frequency elements and tall common determination for high-frequency components.

Here two input images are taken. Firstly, we took illumination adjusted images output and secondly, we took the color corrected image as input. Then we separated the high-frequency and low-frequency elements from the image. Whereas the wavelet transforms both dimension of is used. Firstly, the high pass and low pass filter used on the rows, after that it is used on the columns. At a point it provides horizontal approximation value when a low pass filter is used on the rows and we get horizontal details by using high pass filter. The sub-signal has the highest frequency equivalent to half of the first, created from the low pass filter on the columns of the horizontal approximation and horizontal information, low pass filters and high pass filters are once again used, carrying around four sub-images.[10]: rough picture, horizontal detail, vertical detail, and diagonal detail separately. In figure 4 the one level decomposition of the input picture has shown [1].

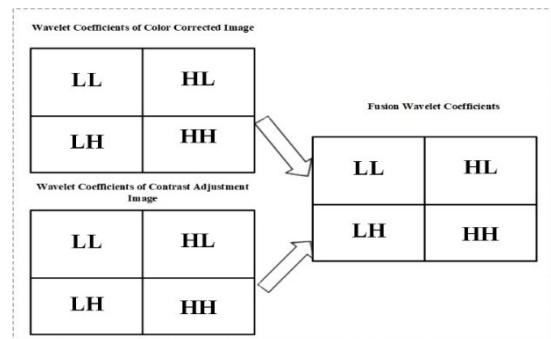

Figure 4: 2D wavelet-based image decomposition of level two.

The pictures are used as an input for their coefficient to be decomposed and composed inversely. Then the wavelet transform is used separately to get the modified image as a final image. Up sampling completes the decomposition of wavelet transformation, and down sampling is used for the converse composition.

Figure 5: 2D decomposition of level two, fusion of coefficients and Output Image

The output images of illumination adjusted image and the color-enhanced image are used as the input for DWT decomposition in figure 5. From there, no opposite change is applied to the coefficients of its decomposition and fused utilizing the maximum estimations of the coefficients.

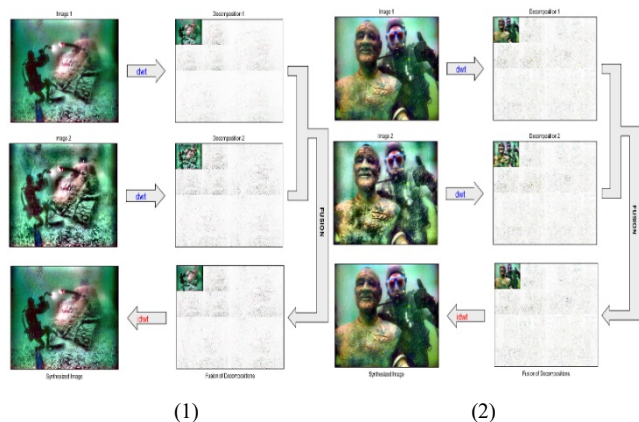

Figure 6: 2D decomposition of level two, fusion of coefficients and synthesized image (1) & (2) of the proposed method

Figure 7: (1) Fusion Output 1 (2) Fusion Output 2

3.4. Super Resolution

Super-resolution could be a method of imaging that progresses the resolution of an imaging framework, additionally, it could be a prepare of combining a sequence of low-resolution pictures to create the next determination picture or arrangement. In arrange to demonstrate the execution of this strategy, it was being utilized on the stacked dataset(images), compared with diverse strategies there had been prepared the taking after stack dataset(images) utilizing code.

After applying the bi-cubic interpolation procedure, the VDSR (Very-Deep Super Resolution) method has been applied to the image. VDSR refers to a convolutional neural network engineering intended to perform single image super-resolution [11]. The VDSR learns the retailing among low-and high-goals images. This retailing is conceivable on the grounds that low-resolutions and high-resolution images have comparative image content and vary principally in high-recurrence subtleties. VDSR utilizes a leftover learning methodology, implying that the system figures out how to evaluate a lingering image. With regards to super-resolution, a leftover image is a distinction between a high-resolution reference picture and a low-resolution image that has been upscaled utilizing bi-cubic interpolation to coordinate the size of the allusion image. A remaining image holds data of high-frequency subtleties of an image. The residual image from the luminance of a color image is found by the VDSR network. VDSR is prepared to utilize just the luminance channel since human understanding is more sensitive to alternate in brilliance than to alternate in color. For a scale factor, the size of the reference image to the size of the low-resolution image is expected. As the scale factor expands, SISR turns out to be all the more not well presented in light of the fact that the low-goals image loses more data about the high-frequency image

content. By utilizing a huge responsive field VDSR takes care of this issue. This model trains a VDSR network with different scale factors utilizing scale augmentation. Scale augmentation improves the outcomes at bigger scope factors on the grounds that the network can exploit the image context from littler scale factors. Also, the VDSR system can sum up to acknowledge images with inter-scale factors.

4. Result and Discussion

The results are described as follows;

Output	6.8683	7.5112	7.8738

5. Conclusion

In this article, by illumination improvement and color correction with fusion technique, we defined super resolution-based

underwater image enhancement that will ensure successful clarity enhancement and recovery of blurred underwater image. An image taken underwater faces so many problems like blurring and distraction, attenuation in water etc. For recovering this problem, we have proposed a method that has been used to correct all faced problems. Initially we took a hazy underwater image then we used illumination adjustment and color correction method on the image, after getting two outputs from illumination adjustment and color correction, we have used the fusion technique on those two images and combined them by the fusion technique to get an effective fused image as output. That clarity of the image has been improved after that. Then we have applied the super resolution method on the image obtained from fusion technique. Applying super resolution, the clarification of the image has been more-high. On the other-hand if there is any blur or noise in the image it will be removed and sharpened and we will get a high-resolution image. In Table 1 shows that the performance of the Entropy, Peak Signal-to-Noise Ratio (PSNR), Mean Square Error (MSE), Root Mean Square Error (RMSE) and Structural Similarity Index (SSIM) result for the images which are used for analysis. The comparison between our output image and [1], [12] authors output image in Table 2, and its clearly describes that the output image has a higher entropy value from them, and it's as desired for the quality of a good image. From here we can clearly clarify that we can achieve a more effective clear image from a hazy image.

6. Future Works

Our plan is to focus on addressing the inhomogeneous dispersion and artificial lighting problems in Super Resolution, in future. On the other hand, in addition to hydrophyte robot inspection and IOT, particularly in vision systems, underwater inspection and observation tasks.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Robotic arms or industrial robots are a machinery that is widely used in the medical and military industries because it is a flexible, highly accurate and reliable. It is very necessary to work in complex tasks requiring more accuracy than humans can work. This paper presents an estimate of the standard uncertainty of 6 DOF robotic arm, KUKA KR5 ARC robot, and describes the experimental setup of a laser tracker to measure the position of the reflector mirror installed on a robot end-effector. This research describes the method of testing and experimenting to calculate the errors of each joint by using the inverse kinematic model, calculating the actual angle of their joint in comparing it with a nominal joint angle. The Jacobian matrix was applied to calculate the robotic position error. The calculation of uncertainties of each joint was conducted by using the Jacobian matrix to calculate the uncertainty in the robot and the four points testing were designed for estimating the error value and uncertainty value. The results showed that the error and uncertainty of each test point were within the range of the average error and the average uncertainty of the robot specification. The position errors and the position uncertainties of all test points within the robotic moving space were calculated and estimated by the proposed method and model. Therefore, the position error tolerance of each required moving target point must be smaller than the position errors and the position uncertainties that are estimated from this proposed model. These estimated robot linear position end effector uncertainties were used to compare and adjust the robotic path based on the required robotic position target and tolerance control.

1. Introduction

In the modern manufacturing industry, technology is applied, whether it is software or hardware or a combination of the both. The 6 degrees of freedom (DOF) robotic arm is one of the most sought-after combination machinery, as is designed to be flexible for mimicking human arm functions. This is consisting of arm parts and automation control parts that are accurate and precise. However, it is like a common machine. When used for a long time or used in improper conditions, it will result in deterioration. As a result, lower accuracy does not meet the specified features, and also result in a loss of reliability. From such problems, the researchers created the idea of estimating random errors and standard uncertainty of the 6 DOF robot, which researchers have determined that the joints are the most moving parts. As a result, this is the source of the most common errors. This research develops the principles of calculating random error and uncertainty that occurs with every joint and robot.

In this research, there are two objectives: 1) Estimate the random error of each joint and estimate the robotic error. and 2) Estimate the uncertainty of each joint and estimate the robotic uncertainty. When the experiment was set up, the laser tracker was applied to measure the position of the reflector installed at the end-effector. This paper is an extension of work originally presented in 2020 IEEE 7th International Conference on Industrial Engineering and Applications (ICIEA) [1].

Over the years, many researches has been conducted in analyzing the kinematic and kinematic errors of robotic arms and other machines, such as: a study of kinematics model of Staubli RX 90 robot 6 DOF robotic arm and position of robot control was calculated and tested by writing the English Alphabet [2]. Focus on machine tool random errors in a 3D workspace and offered new models that help predict product tolerances caused by uncertainties of a machine tool [3]. The new approach with a 2D manifold that reduces the dimensionality of the workspace to improve the efficiency of error compensation for robotic machining [4]. The photogrammetry-based measurement to compensate the

*Corresponding Author: Chana Raksiri, Bangkok, fengcnr@ku.ac.th

machining errors from parts and validated results [5]. A proposal for a guideline for a 3D-Piezo compensation mechanism unit that could quickly and accurately adjusted the spindle position to optimize robotic machining [6]. The evaluate the deviations for calculating the efficient robotic trajectory from aligned optically scanned point clouds [7] and the analysis of positioning accuracy and the kinematic parameters of robotic end-effector influenced by both internal and external temperature factors [8]. In addition, a study was proposed on improving the performance of the SEIKO D-TRAN RT3200 robot by studying the repeat control [9]. Improvement in the performance of robotic arms to have higher accuracy. Analyzed the positioning error value and then compensate for it [10]. Mathematical modeling to analyze the geometric errors of joint assembly affecting the end-effector of the 6 DOF robot was the one importance factor for robot accuracy [11]. Calibration and determination of the measurement uncertainty of robotic arms is an important issue in the confidence of the robot. There have been several research essays that discuss the principle of the measurement uncertainty such as: The kinematic error model presented by classifying the source of the error value by designing calibration methods compared to conventional calibration [12]. Applied laser interferometer to measure roundness [13]. Proposed the application of laser interferometer for calibration grade 2 gauge blocks and applied it for warhead roundness measurement [14-15]. Calibrated 6 DOF robotic arm using the Circle point analysis (CPA) method to configure a circle to measure and use the Monte Carlo method to find out the measurement uncertainty [16] and used a new method to calibrate the end-effector of 6 DOF robotic arm [17]. As mentioned above, in this research, there are the action plan is as follows: 1) Preparation of equipment and tools, 2) Learnt the involved methods and theories such as principle of the measurement method, kinematics model and the measurement uncertainties 3) experimental design and testing 4) result and conclusion.

2. Materials and Methods

2.1. Robotic arm

Robotic arms are machines that are developed for many characteristics, but at the same time are precise and accurate. This research presents an estimate of the standard uncertainty of 6 DOF robotic arm, focusing on welding robotic arms. The robotic arm used in this research is the KUKA KR5 ARC as shown in Figure 1 and D-H parameters and joints limit as shown in Table 1.

Table 1: KUKA KR5 ARC D-H parameters

Link (n)	Link twist (α_{n-1})	Link length (a_{n-1})	Link offsets (d_n)	Joint angles (θ_n)
1	180°	0	-400	θ_1
2	90°	180	0	θ_2
3	0°	600	0	θ_3-90°
4	90°	120	-620	θ_4
5	-90°	0	0	θ_5
6	90°	0	-115	θ_6
7	180°	0	0	180°

Figure 1: KUKA KR5 ARC robot

2.2. Laser Tracker

Laser tracker is a 3D measurement device, which is a standard metrology in precision, accuracy and reliability. This research uses the FARO laser tracker ION model as shown in Figure 2 to measure the position of the laser reflector installed at the end-effector.

Figure 2: FARO laser tracker ION model

2.3. Kinematic model

Kinematics describes the movement of object points and systems of bodies (groups of objects), regardless of the force that causes movement. Kinematics is a major part of mechanics which is often referred to as the "geometry of movement". The kinetic problem begins by explaining the system's geometry and declaring the initial conditions of the value, position, speed and/or acceleration within the known system. From a geometric point of view, it can locate the speed and acceleration of any unknown part of a system [18].

Robotic kinetics relies on differentials to describe the relationship between joints and links from the base to the end-effectors. The frame attached to the robotic joints is serialized like a chain. The relationship of one frame versus another frame from the bottom up will result in a conversion equation. This is the relationship of the base frame against the tool frame [19].

2.3.1. Forward kinematic

Forward kinematics are the mathematical model to compute the coordinates and directions (homogeneous conversion form) of robot end-effector positions relative to the function of the robot angles of each joints. This paper followed Denavit and Hartenberg (D-H) by choosing the reference frames in a robotic application

that Jacques Denavit and Richard S. Hartenberg proposed. In this convention, the coordinate frame is attached to the joints between the two links so that one conversion involves joint [Z] and the second frame is linked to the link [X], converting coordinates with serial robots that contain n links to the robot's equation format. D-H convention determines each conversion A_n with a multiple of fundamental conversions, respectively. The transformation matrix can be written as follows:

$${}_{n-1}^nT = A_n = \begin{bmatrix} C\theta_n & -S\theta_n & 0 & a_{n-1} \\ S\theta_n C\alpha_{n-1} & C\theta_n C\alpha_{n-1} & -S\alpha_{n-1} & -d_n S\alpha_{n-1} \\ S\theta_n S\alpha_{n-1} & C\theta_n S\alpha_{n-1} & C\alpha_{n-1} & d_n C\alpha_{n-1} \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1)$$

where, A_n is the homogeneous matrix that describes the movement of the frame of each contiguous joint ($n-1$ and n). θ_n is the joint angle of the i th joint, d_n is the link offset of the i th joint, a_n is the link length of the i th joint, and α_n is link twist of the i th joint. $S\theta_n = S_n = \sin(\theta_n)$, $S\alpha_n = \sin(\alpha_n)$, $C\theta_n = C_n = \cos(\theta_n)$ and $C\alpha_n = \cos(\alpha_n)$.

The parameters were replaced in Table 1 in (1), and multiplied all the matrixes in order. It is the last matrix that shows the position and direction of the end-effector compared to the base can be displayed as follows:

$${}^7_0T = A_1 A_2 A_3 A_4 A_5 A_6 A_7 = \begin{bmatrix} n_x & o_x & a_x & P_x \\ n_y & o_y & a_y & P_y \\ n_z & o_z & a_z & P_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (2)$$

In this research, the linear position of end-effector is determined, which shows the position in the coordinates x, y, and z, as shown in (3).

$$\begin{aligned} P_x &= C_1[a_1 + a_2 C_2 + S_{23}(a_3 + d_6 C_4 S_5) - C_{23}(d_4 + d_6 C_5)] \\ &\quad + d_6 S_1 S_4 S_5 \\ P_y &= -S_1[a_1 + a_2 C_2 + S_{23}(a_3 + d_6 C_4 S_5) - C_{23}(d_4 + d_6 C_5)] \\ &\quad + d_6 C_1 S_4 S_5 \\ P_z &= -d_1 - a_2 S_2 + C_{23}(a_3 + d_6 C_4 S_5) + S_{23}(d_4 + d_6 C_5) \end{aligned} \quad (3)$$

2.3.2. Inverse kinematic

In the previous section, the robot forward kinematics are the mathematical equations, used to calculate the position and direction of the end-effector frame compared with base frame when the variables joints ($q_0, q_1, q_2, \dots, q_n$) are known. On the other hand, to know the variable joints ($q_0, q_1, q_2, \dots, q_n$), when determining the homogeneous matrix at the end-effector frame compared to the base frame (n_0T), the resulting relationship is called inverse kinematics.

For general cases in robotics, the inverse kinematics calculation of the robot is more complex than the forward kinematics problems because the results can occur in 3 different ways consisting of no solution, unique solution, and many solutions.

2.3.3. Jacobian matrix

The Jacobian matrix is a matrix that shows the relationship between the error of the end-effector and the 6 joints error of the robot. The Jacobian matrix can be found in the analysis of the forward kinematic, as shown in (4).

$$dX = J d\theta_i \quad (4)$$

where, $d\theta_i$ are the angle errors of 6 axis ($i=1, 2, 3, \dots, 6$).
 J is Jacobian matrix.

Jacobian's pattern is in the form of a 6x6 matrix, which is based on (5):

$$J_{6 \times 6} = [J_1 J_2 J_3 J_4 J_5 J_6] \quad (5)$$

$$J = \begin{bmatrix} J_{11} & J_{12} & J_{13} & J_{14} & J_{15} & J_{16} \\ J_{21} & J_{22} & J_{23} & J_{24} & J_{25} & J_{26} \\ J_{31} & J_{32} & J_{33} & J_{34} & J_{35} & J_{36} \\ J_{41} & J_{42} & J_{43} & J_{44} & J_{45} & J_{46} \\ J_{51} & J_{52} & J_{53} & J_{54} & J_{55} & J_{56} \\ J_{61} & J_{62} & J_{63} & J_{64} & J_{65} & J_{66} \end{bmatrix}$$

The six joints of the robot are all revolute (R). Therefore, the Jacobian matrix can be calculated as follows:

$$J = \begin{bmatrix} z_{i-1} \times (o_n - o_{i-1}) \\ z_{i-1} \end{bmatrix} \quad (6)$$

where, z_{i-1} is the value of the top 3 elements in column 3 of the matrix T_0^i
 o_i is the value of the top 3 elements in column 4 of the matrix T_0^i

When a robot moves, the linear position error for x, y and z direction of the end-effector, can be written in a partial derivative of equation 3 relative to the angle in each of the changing joints. The Jacobian components that are affected by the x, y and z linear position of end-effector in Jacobian matrix as follows:

$$\begin{aligned} J_{11} &= -S_1[a_1 + a_2 C_2 + S_{23}(a_3 + d_6 C_4 S_5) - C_{23}(d_4 + d_6 C_5)] \\ &\quad + d_6 C_1 S_4 S_5 \\ J_{12} &= C_1[C_{23}(a_3 + d_6 C_4 S_5) + S_{23}(d_4 + d_6 C_5) - a_2 S_2] \\ J_{13} &= C_1[C_{23}(a_3 + d_6 C_4 S_5) + S_{23}(d_4 + d_6 C_5)] \\ J_{14} &= d_6 S_5(C_1 S_{23} S_4 + S_1 C_4) \\ J_{15} &= d_6(C_1 S_{23} C_4 C_5 + C_1 C_{23} S_5 + S_1 S_4 C_5) \\ J_{16} &= 0 \\ J_{21} &= -C_1[a_1 + a_2 C_2 + S_{23}(a_3 + d_6 C_4 S_5) - C_{23}(d_4 + d_6 C_5)] \\ &\quad - d_6 S_1 S_4 S_5 \\ J_{22} &= S_1[a_2 S_2 - C_{23}(a_3 + d_6 C_4 S_5) - S_{23}(d_4 + d_6 C_5)] \\ J_{23} &= S_1[-C_{23}(a_3 + d_6 C_4 S_5) - S_{23}(d_4 + d_6 C_5)] \\ J_{24} &= d_6 S_5(S_1 S_{23} S_4 + C_1 C_4) \\ J_{25} &= -d_6(S_1 S_{23} C_4 C_5 + S_1 C_{23} S_5 - C_1 S_4 C_5) \\ J_{26} &= 0 \\ J_{31} &= 0 \\ J_{32} &= -[S_{23}(a_3 + d_6 C_4 S_5) - C_{23}(d_4 + d_6 C_5) + a_2 S_2] \\ J_{33} &= -S_{23}(a_3 + d_6 C_4 S_5) + C_{23}(d_4 + d_6 C_5) \\ J_{34} &= -d_6 C_{23} S_4 S_5 \end{aligned}$$

$$J_{35} = -d_6(S_{23}S_5 - C_{23}C_4C_5)$$

$$J_{36} = 0$$

2.4. Principle of measurement the random error of individual robotic joints method

In this research, the principle of the proposed measurement method measures the positions the end-effector in 3 dimensions system (x, y, z) that is affected from the rotation of a joint when the others are locked. Figure 3 shows an example of the measurement principle of joint 2. After the measurement system setup, the program instructs the end-effector to move to the specified position $(P_1, P_2, P_3, \dots, P_n)$. The laser tracker measures the position according to the specified cycle, the identification of rotation plane and rotation center are shown in section 2.4.1 and 2.4.2.

Figure 3: Basic principle of the measurement method for J_2 random joint error setting

Identifying a rotating plane of the robotic arm joints aims to create a circular arc from the rotation of the joints measured in the Cartesian area. This arc has a measurement points m . The rotation plane in the Cartesian space can be calculated as follows:

$$z = Ex + Fy + G \quad (7)$$

The previous equation is where x, y and z are coordinates points in the rotation plane. E, F and G are the rotation plane coefficients.

In the rotation plane, the adjustment of the measurement point (x_i, y_i, z_i) when $k=1, \dots, m$ is derived from the minimization problem as follows:

$$J_z = \sum_{k=1}^m (z - z_k)^2 \quad (8)$$

2.4.2. Identification of rotation center

In theory, the trajectory of the m point in the arc of the circle of a rigid body, this circle plane is perpendicular to the fixed axis. However, in the practice, there are some factors such as vibration during rotation and the non-standard assembly etc. So, that result in the trajectory of the m points may not be completely circular and assume that the theoretical circular and circle trajectory have very few deviations, thereby, a circle equation from the equation (9) is used to fit these points. So, the rotation plane of robotic arm joints can be calculated. Using the least square method was done

in order to identify the circle on the circle plane. A standard form of a circle equation is as follows:

$$(x - x_c)^2 + (y - y_c)^2 = r^2 \quad (9)$$

The previous equation is where (x_c, y_c) is the rotation center. r is the radius of the circle. From (3) can be rewritten as follow:

$$w = x^2 + y^2 = Ax + By + C \quad (10)$$

The previous equation is where A, B and C are the coefficients of the circle center in 3D system. Then, there are the sets of measured (x_i, y_i, z_i) when $i=1, 2, 3, \dots, m$ is derived from the minimization problem as follows:

$$J_w = \sum_{k=1}^m (w - w_k)^2 \quad (11)$$

2.4.3. Experiment setup

This system consists of 3 important parts: 1) robotic arm. 2) laser tracker. and 3) installation of the reflector at the end effector as shown in Figure 4.

Figure 4: The 6 DOF KUKA KR5 ARC robot experimental setup

- Assign the end-effector move to the first position P_1 .
- Unmeasured joints are locked from moving. After that measured the points $P_1, P_2, P_3, \dots, P_n$ are fitted with a plane in the Cartesian space.
- On the determined plane, specifies the points on the arc of the circle $P_1, P_2, P_3, \dots, P_n$ and determines the center of the circle O .
- Measured 30 times repeat for every points m .

2.5. Evaluation for Measurement Accuracy

In a high-accuracy and high-precision measurement system to increase measurement and reliable confidence levels, measurement accuracy is required to increase the confidence and

reliability of the measurement. Therefore, measurement accuracy assessment is required. This evaluation compares the deviation (errors) between frame $\{E_i\}$ and frame $\{E_i'\}$ where, frame $\{E_i\}$ is calculated by the proposed method and frame $\{E_i'\}$ is calculated by forward kinematic of robotic arm.

2.5.1. Joint errors

Joints errors are due to repeatability of measurement and can be calculated as the difference between actual (measurement) and nominal angle. The position of end-effector is converted to the angle of each joint with inverse kinematics. The actual angle as shown in (12-17):

$$\theta_1 = \text{Atan2}(-\bar{n}_y, \bar{n}_x) \text{ or } \theta_1 = \text{Atan2}(\bar{n}_y, -\bar{n}_x) \quad (12)$$

$$\theta_2 = \text{Atan2}(ad - bc, ac + bd)$$

$$\text{or } \theta_2 = \text{Atan2}(-ad + bc, -ac - bd) \quad (13)$$

$$\theta_3 = \text{Atan2}(d, c) + \text{Atan2}(\pm\sqrt{c^2 + d^2 - e^2}, e) \quad (14)$$

$$\theta_4 = \text{Atan2}(a, b) \text{ or } \theta_4 = \text{Atan2}(a, b) + a_1 \quad (15)$$

$$\theta_5 = \text{Atan2}(\pm\sqrt{a^2 + b^2}, c) \quad (16)$$

$$\theta_6 = \text{Atan2}(a, b) + \text{Atan2}(\pm\sqrt{a^2 + b^2 - c^2}, e) \quad (17)$$

for θ_2 . $a = -d_1 + d_6\bar{n}_z$, $b = -(a_1 + d_6\bar{n}_x C_1 - d_6\bar{n}_y S_1)$, $c = -d_4 C_3 + a_3 S_3$ and $d = a_3 C_3 - d_4 S_3 + a_2$

for θ_3 . $c = 2a_2 a_3$, $d = -2a_2 d_4$ and $e = a^2 + b^2 - (a_3^2 + d_4^2 + a_2^2)$

for θ_4 and θ_5 .

$$a = (p_y C_1 + p_x S_1)/d_6, b = ((p_z + d_1)C_{23} - (a_2 + a_3)S_{23} - a_3 + (p_y(C_{123} - C_{1-2-3}))/2 + (p_x(S_{123} - S_{1-2-3}))/2)/d_6$$

$$\text{and } (c = (p_z + d_1)S_{23} - a_1 C_{23} - a_2 C_3 + (p_y(S_{123} - S_{1-2-3}))/2 + (p_x(C_{123} - C_{1-2-3}))/2 - d_4)/d_6$$

for θ_6 . $a = C_4$, $b = C_5 S_4$ and $c = o_y C_1 + o_{yx} S_1$

Therefore, the joint errors can be calculated as follow:

$$d\theta_i = \frac{1}{g} \sum_{k=1}^g (\theta_{in} - \theta_{ia}) \quad (18)$$

where, θ_{in} are the nominal angle.

θ_{ia} are the actual (measurement) angle.

g is number of measurement points.

i are the robotic joints ($i=1, 2, 3, \dots, 6$).

2.5.2. Position errors

In this research, the linear position error for x, y and z direction of the end-effector (dx , dy , dz) are determined. Therefore, the position errors in the x, y and z axes at the end-effector as shown in (19-21) respectively.

$$dx = J_{11}d\theta_1 + J_{12}d\theta_2 + J_{13}d\theta_3 + J_{14}d\theta_4 + J_{15}d\theta_5 + J_{16}d\theta_6 \quad (19)$$

$$dy = J_{21}d\theta_1 + J_{22}d\theta_2 + J_{23}d\theta_3 + J_{24}d\theta_4 + J_{25}d\theta_5 + J_{26}d\theta_6 \quad (20)$$

$$dz = J_{31}d\theta_1 + J_{32}d\theta_2 + J_{33}d\theta_3 + J_{34}d\theta_4 + J_{35}d\theta_5 + J_{36}d\theta_6 \quad (21)$$

From that (19-21) can calculate the total error at the end-effector as follows:

$$e_t = \sqrt{d_x^2 + d_y^2 + d_z^2} \quad (22)$$

2.6. Measurement uncertainty

In metrology, measurement uncertainty is an expression of statistical distribution of values caused by measured quantities. Therefore, measurement uncertainty is used in combination with the measurement results to reflect the actual value of the measurement quantity. Especially, when the measurement results are applied to various quality criteria, the results must be applied to the quality criteria. According to international agreements, this uncertainty is based on probability and shows the incomplete of the quantity and it is a non-negative parameter.

Multiple repetitive measurements and calculating standard deviations from re-measuring are among the most common practices in estimating measurement uncertainty. Whether it is a full or partial measurement, it can be repeated. The estimation of the uncertainty received is a standard deviation of the repetitive measurement results, which is a statistical process. It is called type A uncertainty. The type B uncertainty is estimated from other deviation source such as material certificates, specifications, and long-term experience-based assessments [20].

The Expression of Uncertainty and Confidence in Measurement, M3003 [21] and Fundamental Parameter and Application describes how to calculate standard uncertainty.

2.6.1. Type A uncertainty

Type A uncertainty is estimated using statistical principles. By performing measurements, conditions are subject to repeated measurement conditions to see the original iteration or view the distribution of the measured average. The arithmetic mean, or average, of the results should be calculated. If there are n independent repeated values for a quantity Q then the mean value \bar{q} is given by:

$$\bar{q} = \frac{1}{n} \sum_{i=1}^n q_i = \frac{q_1 + q_2 + \dots + q_n}{n} \quad (23)$$

Then the estimated fragmentation of data is calculated from the standard deviation of the n values can compute as follows:

$$\sigma = \sqrt{\frac{1}{n} \sum_{j=1}^n (q_j - \bar{q})^2} \quad (24)$$

Equation (24) gives the standard deviation for sampling from all populations. However, based on the results of a single measurement sample, approximate, $s(q_j)$, can be made from the standard deviation σ of the entire population of possible values from the relation:

$$s(q_j) = \sqrt{\frac{1}{n-1} \sum_{j=1}^n (q_j - \bar{q})^2} \quad (25)$$

The average q will be derived from the exact sample number of n and, therefore, its value will not be the exact average if the infinite

sample number is taken. This uncertainty is called the standard deviation of the mean that can compute as follow:

$$s(\bar{q}) = \frac{s(q_i)}{\sqrt{n}} \quad (26)$$

2.6.2. Type B uncertainty

Estimating type B uncertainty is the other way around. In other words, it uses information from various sources that are academically reliable to consider the assessment. The error element from a source called the systematic error is valued as a type B uncertainty. Therefore, estimating the type B uncertainty requires a lot of knowledge of measurement techniques. In order to be able to identify a source of uncertainty, much of the systematic error is complete. The estimation of uncertainty needs to consider the source of uncertainty values as follows:

- Deviation Instability compared to the reference standard stipulated in the reported calibration uncertainty.
- Calibration of measuring instruments includes accessories and any drift or instability in measuring instruments or readings.
- Resolution and uncertainty during measurement.
- The operational procedure.
- Mistakes caused by the operator.
- The effects from environment.

2.6.3. Combined uncertainty

The type A and B uncertainty values are part of the overall measurement uncertainty value, which can be calculated for the combined standard uncertainty as shown in (27):

$$u_c(y) = \sqrt{\sum_{i=1}^N c_i^2 u^2(x_i)} \equiv \sqrt{\sum_{i=1}^N u_i^2(y)} \quad (27)$$

where $u_c(y)$ is the combined uncertainty, c_i is the sensitivity coefficient and $u(x_i)$ is the standard uncertainty.

2.6.4. Expanded uncertainty

The combined uncertainty that is approximated is considered to have a certain level of confidence which is not suitable enough for laboratory use. Therefore, it is necessary to multiply combined uncertainty with coverage factor k . The expanded uncertainty as follows:

$$U = k.u_c(y) \quad (28)$$

2.6.5. Robot uncertainty

In this research, the uncertainties position errors for x, y and z direction of the end-effector (U_x , U_y and U_z) are determined. Therefore, the uncertainties position errors in the x, y and z axes at the end-effector (U_x , U_y and U_z) as the function of joint uncertainty (U_1 , U_2 , U_3 , U_4 , U_5 and U_6) are shown in (29-31) respectively.

$$U_x = J_{11}U_1 + J_{12}U_2 + J_{13}U_3 + J_{14}U_4 + J_{15}U_5 + J_{16}U_6 \quad (29)$$

$$U_y = J_{21}U_1 + J_{22}U_2 + J_{23}U_3 + J_{24}U_4 + J_{25}U_5 + J_{26}U_6 \quad (30)$$

$$U_z = J_{31}U_1 + J_{32}U_2 + J_{33}U_3 + J_{34}U_4 + J_{35}U_5 + J_{36}U_6 \quad (31)$$

From that (29-31), it can calculate the total uncertainty at the end-effector as follows:

$$U_t = \sqrt{U_x^2 + U_y^2 + U_z^2} \quad (32)$$

3. Results

The research focuses on the study estimating the standard uncertainty of 6 DOF KUKA KR5 ARC robot, considering the 3 key parts of which parameter values used in calculations derived from the experiment as shown in section 3.1-3.2 consist of robotic errors and robotic uncertainties.

3.1. Robotic error

The errors of the robot in this research are divided into two parts: joint errors and position errors.

3.1.1. Average Joint errors

Based on the experiments measuring data from section 2.4, the average joint errors are calculated according to (18).

- Joint 1 average error ($d\theta_1$) equals 0.101° .
- Joint 2 average error ($d\theta_2$) equals -0.287° .
- Joint 3 average error ($d\theta_3$) equals 0.070° .
- Joint 4 average error ($d\theta_4$) equals -0.097° .
- Joint 5 average error ($d\theta_5$) equals 0.026° .
- Joint 6 average error ($d\theta_6$) equals 0.140° .

3.1.2. Average Position errors

When average joint errors are known, the average position errors at the end-effector in x, y and z axis can be calculated according to (19-21).

- Average Position error in x axis (d_x) equals -0.357 mm.
- Average Position error in y axis (d_y) equals -0.303 mm.
- Average Position error in z axis (d_z) equals 0.383 mm.

So, instead of position errors at the end-effector in x, y and z axis in (21), the average robot error (e) is equal to 0.605 mm.

3.2. Robotic uncertainty

The uncertainties of the robot in this research are divided into two parts: joint uncertainties and position uncertainties.

Figure 5: Basic principle of the measurement method and sources of uncertainty

3.2.1. Joint uncertainties

The research is based on the principle of the measurement method and then calculates the average position errors and the standard deviations of position errors of the robotic joints. These

errors show the accuracy, and the standard deviations show the precision of the joints. After that, these values are used to determine the type A standard of joints 1 to 6 of the robot.

Figure 5 shows the basic principle of the measurement method and the sources of uncertainty. In this research, the sources of uncertainty consist of five sources, that uncertainties are type A uncertainty (iU_A) and four sources of type B uncertainty (iU_{Bj}):

where, iU_A are the uncertainty from repeatability.
 iU_{B1} are the uncertainty from resolution of the robot.
 iU_{B2} are the uncertainty from resolution of laser tracker.
 iU_{B3} are the uncertainty from accuracy of laser tracker.
 iU_{B4} are the uncertainty from thermal effect at the reflector fixture.
 i are the robotic arm joints.
 j are the number of the sources of uncertainty.

Table 2 provides a preview of the sources of the uncertainty and the calculation of the total uncertainty of the 1st joint. The uncertainty of each joint are as follows:

The uncertainty of joint 1 (U_1) equal $\pm 0.204^\circ$.
 The uncertainty of joint 2 (U_2) equal $\pm 0.149^\circ$.
 The uncertainty of joint 3 (U_3) equal $\pm 0.076^\circ$.
 The uncertainty of joint 4 (U_4) equal $\pm 0.126^\circ$.
 The uncertainty of joint 5 (U_5) equal $\pm 0.140^\circ$.
 The uncertainty of joint 6 (U_6) equal $\pm 0.115^\circ$.

3.2.2. Position uncertainties (Robot uncertainty)

When the uncertainties of each joint are known. The uncertainties in x, y and z axis at the end-effector can be calculated according to (29-31), the results as the follow:

The uncertainty in x axis (U_x) equal ± 0.225 mm.

The uncertainty in y axis (U_y) equal ± 0.613 mm.

The uncertainty in z axis (U_z) equal ± 0.366 mm.

So, instead of position uncertainties at the end-effector in x, y and z axis in (32), the average robot uncertainty (U_t) is equal to ± 0.748 mm.

The research results showed that the KUKA KR5 ARC robot used in the experiment had the average robot error which (e_t) is equal to 0.605 mm. and with the average robot uncertainty (U_t) is equal to ± 0.748 mm. Then, examples of four test points (P_1 , P_2 , P_3 and P_4) are used to determine the estimated error and uncertainty in each joint from propose model. The position errors and position uncertainties at the end-effector in x, y and z axis can be calculated according to (19–21) and (29–31). The results of the estimated robot position errors and the position uncertainty are shown in the Table 3.

4. Discussion

Objective 1: Measure random errors of each joint and the robot end-effector linear random error in x, y and z direction and average error can be calculated. When comparing the robot error with the specified accuracy, the robot error was found to be slightly higher than the accuracy value. The results of the research process can be compensated in the control system, as it can reduce the error value.

Objective 2: Estimate the uncertainty of each joint and estimate the robot uncertainty. The results show that the uncertainty of each joint at 95% confidence level was quite high and when calculating the average uncertainty of the robot it was quite high too. The high average uncertainty will result in a difference of the robotic error. The biggest uncertainty is the uncertainty from repeatability. It was between 86.21% and 94.48%. This suggests that the uncertainty from repeatability has a significant effect on the total uncertainty, so it is appropriate to consider this factor.

Table 2: The standard uncertainty of joint 1

Type	Value (degree)	Distribution	Divisor	Uncertainty contribution u_i (degree)	Sensitivity coefficient c_i	Effective DOF V_{eff}
iU_A	0.1019	Normal	1	0.1019	1	20
iU_{B1}	0.0019	Rectangular	$\sqrt{3}$	0.0011	1	∞
iU_{B2}	0.0095	Rectangular	$\sqrt{3}$	0.0055	1	∞
iU_{B3}	0.0035	Rectangular	$\sqrt{3}$	0.0020	1	∞
iU_{B4}	0.0002	Rectangular	$\sqrt{3}$	0.0001	1	∞
iU_C		-		0.0083		∞
iU_r		Normal k=2		0.2042		∞

Table 3: The estimated position errors and uncertainties for the example of four test points

Points	Target position (mm)			Position errors (mm)				Position Uncertainties (mm)			
	x	y	z	d_x	d_y	d_z	e_t	U_x	U_y	U_z	U_t
P ₁	125	125	125	-0.033	-0.012	0.445	0.447	± 0.164	± 0.163	± 0.177	± 0.291
P ₂	225	225	225	-0.118	0.182	0.414	0.467	± 0.164	± 0.163	± 0.177	± 0.291
P ₃	225	25	225	-0.125	-0.077	0.465	0.488	± 0.159	± 0.161	± 0.185	± 0.292
P ₄	25	25	25	-0.050	-0.093	0.199	0.225	± 0.168	± 0.159	± 0.178	± 0.292

Therefore, the results from Table 3, the position errors and the uncertainties of all test points within the robot moving space are calculated and estimated by the proposed method and model. Therefore, the position error tolerance of each required moving target point must be smaller than the position errors and the uncertainties that are estimated from this proposed model.

5. Conclusions

In this research, it describes the method of testing and experimenting to calculate the errors of each joint, and calculating the actual angle of their joint to compare with a nominal joint angle. The Jacobian matrix was applied to estimate the robot position error. The estimation of the uncertainties of each joint by using Jacobian matrix was done to estimate the robot position uncertainty. The research results showed that the KUKA KR5 ARC robot used in the experiment average robot error (e_i) was equal to 0.605 mm. and with the average robot uncertainty (U_i) being equal to ± 0.748 mm.

The example of the four test points (P_1 , P_2 , P_3 and P_4) determined the estimated error and uncertainty in each joint from proposed model. The position errors (e_i) was 0.447mm, 0.467 mm, 0.488 mm and 0.225 mm respectively. The position uncertainty (U_i) was ± 0.291 mm, ± 0.291 mm, ± 0.292 and ± 0.292 mm. The position errors and the uncertainties of all test points within robot space moving were calculated and estimated by the proposed method and model. Therefore, the position error tolerance of each required test point must be smaller than the position errors and the uncertainties that are estimated from this proposed model.

ABSTRACT

This study tests the feasibility of manufacturing concrete blocks made of recycled materials. The paper is an extension of work originally presented in ASET conference in Dubai. The paper, depicts and analyzes how the characteristics of the blocks (strength/durability) are affected by the presence of recycled concrete ingredients (recycled aggregate (RA)) and recycled water (RW). The recycled materials (RA and RW) were mixed in 16 different configurations; from each one 10 samples were prepared for testing. In each concrete configuration the RA and RW gradually replaced the fresh materials at 25%, 50%, 75%, and 100%. The RA moderately impacted the bearing capacity but significantly impacted the durability. The results show that using recycled aggregate decreases the bearing capacity by 22% (at the 100% replacement), and the recycled water slightly affected the bearing capacity (at the 100% replacement). To boost the durability, the ground granulated blast furnace slag (GGBS) was used, in the concrete mix, instead of the ordinary Portland cement (OPC). The GGBS was used at 3 magnitudes: 25%, 50%, and 75% of OPC. As a result the carbon foot-print footprint (1000 kg/m^3) was significantly lowered. Besides, the strength and durability of the blocks are reasonably enhanced. Generally, producing blocks from recycled materials is economical and feasible. The use of GGBS helps to lower the carbon footprint and enhance the strength and durability.

1. Introduction

The volume of construction waste (CW) produced in the countries of the Gulf Cooperation Council (GCC), especially in the UAE, is increasing due to on-going developments activities and construction projects. Dubai alone produces huge amount of waste from construction activities (5,000 tons/day). This amount accounts for around 70% of the total solid waste generated [1]. Almost the whole amount of the CW is dumped into landfills posing hazards to the local and regional environment. Therefore, there is a necessity to devise methods for utilization of this huge amount of the construction waste produced [2].

Worldwide many studies have been conducted looking for alternatives to reduce construction waste and hence preserve the natural resources [3], [4]. Completely recycling construction waste, is one of best alternatives have been tested. Recycling of construction waste preserves the virgin natural resources and reduces its negative impacts on the environment. Construction waste recycling gains importance because it provides the construction industry with huge amount of ingredients for

construction applications (aggregate and sand). The recycled aggregate and sand are widely used now in the construction industry applications; road subbase, back-filling, and pipelines bedding material [5], [6]. Significant amount of research efforts have been directed to study the properties of these materials (sand and aggregate) and their effects on construction quality [7]-[14]. In general, compared to the fresh aggregate, the RA was found to have higher water absorption, lower bulk density, and lower specific gravity. The water absorption is higher due to the fact that the RA absorbs water available for hydration of cement. It is reported that water absorption greatly affects the workability and the strength of the concrete [8]. Opposite to that, a recent research reported that with thorough cleaning the RA can have low water absorption [9]. However, the outcome of the most of the research done show that the properties of concrete made of recycled materials (recycled concrete, RC) vary in wide limits, sometimes are even opposite, but generally, compared to the normal fresh concrete (NC), the RC was found to have reduction in compressive strength and increase in water absorption and porosity (decrease in durability) [11]-[13]. Nonetheless, the mechanical properties of concrete structures (cubes, cylinders, and beams) made from recycled materials (RM) is well documented,

*Corresponding Author: Elgaali, P.O. Box: 15825, Dubai, UAE, 971 552493085, eelgaali@hct.ac.ae

however blocks made from RM is not yet widely known. Therefore, the main objective of this paper is to examine the properties (bearing capacity and durability) of concrete blocks made of recycled materials.

Globally and in the UAE, hollow blocks are widely used as a building material in the construction of non-load-bearing walls. Blocks are produced with hollow centers to reduce weight and improve insulation. They are characterized to be light weight and require low maintenance. The block industry is expected to absorb huge amount of the recycled materials.

This paper also aims to test the feasibility of using recycled wastewater in blocks' manufacturing. Dubai generates huge quantity of wastewater every day (around 4 MGD). Presently, this large quantity of wastewater is treated, recycled, and widely reused in different activities such as: irrigation of the public greeneries, stabilization of loose soil, and more recent casting of concrete [15].

For long time, fresh water has been widely used in concrete industry. Unfortunately, nowadays fresh water, around the globe, neither comfortably obtainable nor affordable. Therefore, recycling and reusing of wastewater in concrete industry have been under investigation for a while. According to EN 1008 (2002) and ASTM C 94 the recycled wastewater is well qualified to be used in concrete mixing (Table 1) [16], [17]. Besides, the cost of the recycled water is less than the one of the potable water, especially in this region where the potable water is produced by desalination of the sea water. The properties of concrete - setting, hardening, strength, and durability - were proven to be drastically affected by the characteristics of the water used in concrete casting. However, few studies so far have focused on studying the effect of the recycled water on the concrete quality [1]. As such, this research aims to contribute to the body of literature that examines how the RA and RW impact the quality (strength/durability) of blocks made of recycled materials.

Reducing the carbon foot print (CFP) of the concrete industry was one of the goals of this study. The relatively high carbon foot print (100 kg/m^3) that cement (OPC) put on environment is already documented [9]. One approach to alleviate such high CFP is by replacing the OPC with a material has lower carbon foot print. The ground granulated blast furnace slag (GGBS), is one of the materials that is widely used to replace the cement to lower the carbon footprint and enhance the durability [9]. The GGBS is a secondary product derived from manufacturing process of steel. Therefore, it is used here, as a green material, to make the concrete more durable and reduce the CFP. Hence, excluding the tiny amount of the OPC that was not replaced, the concrete mixtures configured in this study practically could be considered completely recycled concrete or environmentally called "green concrete".

The recycled aggregates and water (RA and RW) were used to prepare concrete samples according to the mix design given in Table 2. Sixteen mixes of concrete were designed and 160 specimens were prepared. In the concrete mixes 25%, 50%, 75%, and 100% of the fresh aggregate and water were replaced by recycled aggregate and recycled water. In order to enhance the durability and carbon foot print 25%, 50%, and 75% of the OPC

in the concrete mixes were replaced by GGBS. The results are presented and discussed in section 3 of this paper.

2. Materials and Methods

2.1. Recycled Aggregate Materials

The recycled aggregate used in this research, was obtained from a recycling plant for demolition and construction waste in Dubai, UAE. Nowadays, almost the whole amount of the construction and demolition waste is recycled in aggregate of high-quality for customers across the country Figure 1.

(a) Input Materials

(b) Output Material

Figure 1: Recycling of Construction Waste in Dubai, UAE

In order to determine the quality of the RA, several samples were collected (grabbed), processed, cleaned, and mixed in representative samples for laboratory testing. Then the following tests were conducted:

- Sieve Analysis.
- Water absorption and Specific gravity.
- LA abrasion.

Figure 2 shows the sieve analysis result. The figure shows that the RA does not meet the specifications set by Dubai Municipality. In order to use this materials, it has to be blended to meet the specifications.

Figure 2: Sieve analysis results

Figure 3 shows the result of the water absorption and specific gravity test. Five representative samples were tested. The figure shows that the RA meets the specifications set by ASTM's construction standards. The values of water absorption are less than 2%; the values of the specific gravity are greater than 2.6% (the permissible limits set by ASTM).

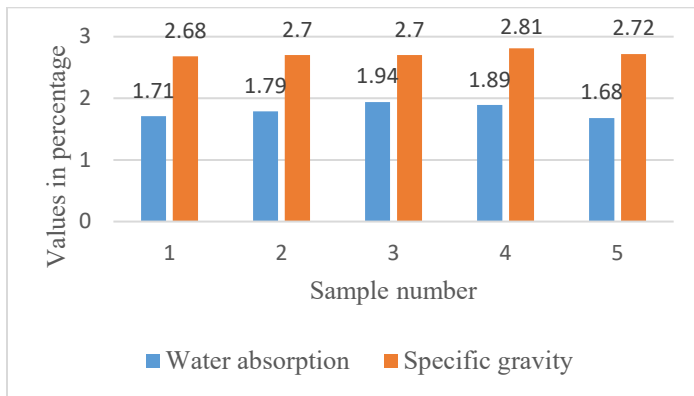

Figure 3: Water absorption and specific gravity test results

Figure 4: LA abrasion test results

Figure 4 shows the result of the LA abrasion test. Five representative samples were tested. The figure shows that the RA meets the specifications set by ASTM. The values of abrasion are less than 30% (the permissible limits set by ASTM).

However, the average measured density and water absorption of the recycled aggregate used in this study were found to be 2.51 t/m³ and 1.8%, respectively.

2.2. Recycled Wastewater

The water used in the concrete mixing in this research, was obtained from sewage treatment plant in Dubai. The wastewater was conventionally treated. In the conventional way, the wastewater is treated through different stages starting from primary treatment to advanced (tertiary) treatment. The advanced treatment is designed mainly to remove the nitrogen and the phosphorus to control eutrophication [18]. Compared to the standards (Chloride 1000, Sulfate 2000, Alkali carbonates and bicarbonates 1000, and Total dissolved solids 2000 mg/L), the characteristics of the recycled water used in this study were found to be acceptable by the masonry blocks standards authority in Dubai [1]. Laboratory analysis results reported the following characteristics of the recycled water: pH 7.704 (standard usually ranges from 7 to 9), Chloride 480, Sulfate 197, Alkali carbonates and bicarbonates 132, and Total dissolved solids 1126.5 mg/L. Table 1, shows the physical and chemical properties of the treated water used in this research.

Table 1: Physical and Chemical Properties of Treated Wastewater

	Units	Min	Max	Average
Temp	(°C)	18	25	20
pH		7.59	7.84	7.704
Cond.	(uS/cm)	1,915	2,400	2203.82
TDS	(mg/l)	1,007	1,218	1126.5
Turbidity	(NTU)	0.6	2.9	1.7
TSS	(mg/l)	2	7	4
VSS	(mg/l)	1	6	2
COD	(mg/l)	23	33	27.0886
sCOD	(mg/l)	24.2	31.4	26.975
cBOD5	(mg/l)	1.64	3.92	2.31
NH4-N	(mg/l)	0.28	5.85	2.56
NO2-N	(mg/l)	0.59	2.16	1.37

2.3. Mixes Design

The study was done in two phases: phase I where the concrete mixes were made of non-processed recycled materials (not sieved or cleaned). Phase II where the concrete mixes were made of processed materials (sieved and cleaned). However, the recycled materials were used to prepare four sets of concrete mixes according to the mix design given in Table 2. Each set consists of four mixes. In total sixteen mixes of concrete were prepared following the same proportions that used in the commercial manufacturing of the blocks. Usually, the blocks mix consist of the following quantities: coarse aggregate: 146 kg of 3/8" and 113 kg of 3/16"; Water: 20 kg; sand: 56 kg; and cementitious materials: 32 kg. As required by the central laboratories in Dubai, out of each mix, ten specimens (blocks) were prepared for testing (160 specimens in total). The blocks are 6-inch hollow blocks (400 X 150 X 200 mm) (Figure 5). This size is selected, because it is the most widely used one in the UAE.

Table 2: Test Matrix

Material Substituted	Percentage			
Recycled Aggregates	25%	50%	75%	100%
Recycled Water	25%	50%	75%	100%
Recycled Water/Aggregate	25%	50%	75%	100%
GGBS	25%	50%	75%	100%

(The GGBS was replaced in a mix of 100% recycled water and 25% of recycled aggregate)

Figure 5: 6-inch hollow block dimensions and weight

In the concrete mixes the RA and RW gradually replace the fresh ones at the following percentages: 25%, 50%, 75%, and 100%. Table 2 shows these replacements more clearly in details. In order to determine the extent of the impact of the recycled materials on the characteristics of the blocks, a mix was prepared from fresh materials and used as a control mix (baseline).

The bearing capacity of each block was tested on a 3000 kN capacity Wizard basic hydraulic machine (Figure 6). Load was applied gradually and continuously until failure.

Figure 6: Testing the block's bearing capacity

3. Results and Discussion

3.1. Effects of Recycled Aggregate

In Phase I, the results show a gradual reduction the axial strength of the block corresponding to the gradual increase in the percentage of the recycled aggregate. It is depicted in Figure 7 that the failure in the bearing capacity (strength) of the blocks ranges from 23% to 46%. The highest reduction was recorded to be associated with the blocks made of 75% replacement. It worth mentioning that the high contents of sand in the RA used, led to the failure of the mix with 100% replacement at early stage (casting stage). However, the results presented are highly supported by some other studies conducted previously [8]-[10]. They documented that the gradual reduction in the axial strength of the mixes directly related to the increase of the percentage of RA. They also depicted that any replacement of RA below 20% has minor effect on the axial strength.

Figure 7: Effect of % recycled aggregate on bearing capacity

In phase II, the results support that the gradual reduction the axial strength of the block corresponding to the gradual increase in the percentage of the recycled aggregate. For better illustration, the results of both phase I and Phase II are compared in Figure 8. The figure shows how the RA impacts the compressive strength of the blocks. The results of phase I show how the presence of sand and dust in the samples of the RA used, led to a significant reduction in the compressive strength extending from 23% to 46%. The results of Phase II show considerable improvement in the blocks quality (Figure 8). At 25% replacement, the block's quality improved from 23% drop to 9% drop in in the strength; at 100% replacement quality of the blocks improved from 100% drop to 22% drop in the strength. In general the magnitude of enhancement in strength extends from 14% to 88%. The enhancement in the blocks' quality is mainly caused by the deep cleaning the RA undergone, in phase II, which results in high removal of sand and dust.

In general, the results presented confirm the inverse relation that governs the magnitude of the block's strength and the percentage of the recycled aggregate (RA).

Figure 8: Effect of % recycled aggregate on bearing capacity

3.2. Effect of Recycled Sand

In Phase I, the results depict how the block's strength was drastically dropped when the percentage of the recycled sand (RS) increased. It is seen in Figure 9 that the failure in the bearing capacity (strength) of the blocks ranges from 90% to 95% when sand is replaced by 25% and 50% respectively.

Figure 9: Effect of % recycled sand on bearing capacity

The presence of clay and silt at high levels in the recycled sand used in this study, caused the mixes with 75% and 100% recycled sand fail at early stage (casting stage). This result is supported by previous research [9].

The results of phase II show how the quality of the RS hindering the process of making sustainable blocks from completely recycled materials. For better illustration, the results of both phase I and Phase II are compared in Figure 10. The figure shows how the RS impacts the compressive strength of the blocks. The results of phase I show how the presence of clay and silt in the samples of the RS used, led to a significant reduction in the compressive strength. The results of Phase II show slight improvement in the blocks quality (Figure 10). At 25% replacement, the block's quality improved from 90% drop to 43% drop in in the strength; at 50% replacement quality of the blocks improved from 95% drop to 69% drop in the strength. In general, the enhancement in the blocks' quality is of small magnitude signifying that using RS at any percentage leads to lower the blocks' quality.

Figure 10: Effect of % recycled sand on bearing capacity

3.3. Effect of Recycled Wastewater

Figure 11 shows that replacing the fresh water in concrete mixes with 100% of RW has very minor impact on the block's quality (bearing capacity). This result signifies the high quality of the RW that characterized by low concentrations of sulfates and chlorides. The deleterious effects of the sulfates and chlorides on the weathering and the durability of concrete are well documented. The high concentrations of the total dissolved solids (TDS) in any water, used for concrete mixing, tend to make the concrete mix less durable [19]. However, the main properties of the RW water used in this study, are presented here for better understanding of the direction of the results in this section. The properties include pH of 7.704, Chloride of 480 mg/l, sulfate of 197 mg/l, Alkali carbonates and bicarbonates of 132 mg/l, and Total dissolved solids of 1126.5 mg/l; compared to standard values of 7 – 9, 1000, 2000, 1000, and 2000 respectively. The results presented, clearly show that the RW is characterized by high quality and can be safely used in concrete industry.

Figure 11: Effect of percentage of recycled water on block's bearing capacity

3.4. Effects of Sulfates and Chlorides

To study the effects of salts on the blocks' quality, the concentrations of the sulfates (SO_3) and chlorides (Cl) were determined and compared to the standards developed by the British standards (BS 1881: Part 124). In 10 specimens the average concentrations of the chlorides and sulfates are determined to be 0.04 mg/l and 0.25 mg/l respectively. The BS set maximum concentration level (MCL) of 0.05%, by mass of concrete, for the chlorides, and 0.5%, by mass of concrete, for the sulfates. Thus, the result obtained here clearly show that the levels of both SO_3 and Cl do not exceed the standards set by the BS. However, both phases I and II show similar results regarding the levels of the chlorides and sulfates.

3.5. Effects of GGBS

Tests conducted to examine the effects of replacing the ordinary cement (OPC) by GGBS. In the concrete mix with 25% RA, 25%, 50%, and 75% of the OPC were replaced by GGBS. As shown in Figure 12, replacing the OPC with 75% GGBS had no effect on the durability, besides no improvement had been shown on the block strength.

Figure 12: Effect of percentage of GGBS on block's bearing capacity

The other two mixes (25% and 50%) both showed improvement in the block strength. As shown (Figure 12), the quality of the blocks improved and the reduction in the axial strength decreased from 22% to 19% (at 25% GGBS) and from 22% to 16% (at 50% GGBS). As reported, the magnitude of improvement falls in the range of 3% - 6%. However, the result show that when the GGBS is more than 50% its influence is negligible.

In general, GGBS was found to boost the durability in any concrete mix. Therefore, to manufacture blocks with high quality, from recycled materials, the blocks industry is encouraged to use GGBS. Besides, the economical (lower cost) and environmental (lower carbon foot print) benefits obtained when GGBS is used instead of OPC.

4. Summary and Conclusions

This study tests how concrete blocks of high quality could be manufactured from ingredients recycled from construction waste (concrete). The paper, depicts and analyzes how the characteristics of the blocks (strength/durability) are affected by the presence of recycled concrete ingredients (recycled aggregate (RA)) and recycled water (RW). The RA moderately impacts the bearing capacity but significantly impacts the durability, while the RW negligibly impacts both. In general it was found that producing blocks from recycled materials is economical and feasible. However, the following specific conclusions are drawn:

4.1. Recycled Aggregate

How the RA affects the qualities of the blocks (strength/durability) was investigated and depicted. The presence of dust on the surface of the RA led to significant drop in the blocks qualities (strength/durability). The magnitude of the drop was estimated to fall in the range of 23% to 46%. When the RA is furtherly sieved, processed, and cleaned the blocks' quality improved a lot. The magnitude of the improvement was estimated to fall in the range of 14% - 63%. It is documented that using RA at magnitude less than 20% has intangible impact on the quality of the blocks.

4.2. Recycled Sand

How the recycled sand (RS) affects the qualities of the blocks (strength/durability) was investigated and depicted. The impacts of RS on blocks; quality was enormous. The impact of RS is very huge ranges between 43% - 95% reduction in the compressive strength. The RS was found to have stronger impact on the blocks' quality when compared to RA and RW. It is documented that using RS at any quantity heavily affects the blocks' quality.

4.3. Recycled Wastewater

How the recycled water (RW) affects the qualities of the blocks (strength/durability) was investigated and depicted. The RW used, is of high quality that matches the standards set by the international and local (Dubai) organizations that manage the masonry blocks industry. The very low levels of the sulfates and chlorides caused the quality of the blocks to be insensitive to the recycled water. However, it can be stated that the high quality of the RW almost has no impact on the blocks' quality (strength and durability). It is documented that using RW at magnitude less or equal to 100% has intangible impact on the quality of the blocks.

4.4. Sulfates and Chlorides

The concentrations of the sulfates (SO_3) and chlorides (Cl) in the blocks, were determined and compared to the standards developed by the international (BS) and local (Dubai)

organizations that manage the masonry blocks industry. The levels of the SO₃ and CL was found to meet the standards set internationally and locally. However, the current levels (0.04 mg/l and 0.25 mg/l) have no impacts on the blocks quality.

4.5. GGBS

Using the ordinary cement (OPC) in concrete mixes, adversely affects the local and regional environment (increase the carbon footprint). Also, using recycled materials in concrete mixes has huge impact on the durability. Therefore, GGBS was tested to replace the OPC to preserve the blocks' quality (durability) and save the environment (reduce CFP). Replacing the OPC with GGBS by percentage exceeds 50% has no positive effect on the quality of the blocks. The outcome of this study documents that using GGBS, in block manufacturing process, helps to lower the carbon footprint and enhance the strength and durability.

Conflict of Interest

No conflict of interest in publishing this paper.

Methodology for Calculating Shock Loads on the Human Foot

Shock Load

ABSTRACT

The leading place among diseases of the musculoskeletal system is occupied by various feet deformations. Clinical movement analysis and posturological examination are required to objectively assess the distribution for load caused by the weight of human body on the feet and its locomotion effect. In normal conditions, the foot is exposed to elastic deformations. When analyzing the foot loads, it's necessary to consider shock loads as one of dynamic load types. The foot is the first to perceive the shock impulse by support reaction, and the further nature for interaction with the environment directly depends on its functional capabilities. However, the foot supporting properties haven't been fully researched. The purpose for this research is to increase the accuracy of estimating the human foot biomechanical parameters, by assessing the dynamic impact, namely short-term shock loads by step cycle relevant phases. This goal is solved by developing a method of static-dynamic load analysis, which allows to estimate dynamic and shock loads on foot and is reduced to determining the capacity coefficients, dynamic and shock loads. In the course of studies, conducted in this research, it was found that the maximum contact per unit time has front section (repulsion phase), then - the rear section (landing phase) and the smallest - the foot middle section (rolling phase), the greater speed and length step – so the greater shock loads coefficient, and their peak falls on the front and rear sections. The practical significance of the obtained results is to improve the existing methods of researching biomechanical parameters by comprehensively assessing by standing and gait features, foot step cycle and support properties.

1. Introduction

The current stage of development for instrument making actualizes the applied aspect for human locomotions analysis. Diagnosis of posture wouldn't be complete without measuring and assessing the state of support-spring foot properties. Clinical analysis for movement and posturological examination (body position examination) are required to objectively assess the effect by foot load distribution on locomotion. In modern biomedical engineering, a fairly promising area is clinical analysis of motor activity - the research of various pathologies of gait and main rack, using biomechanics methods. There is no doubt about the importance of assessing the functional state by musculoskeletal system in patients with orthopedic and neurological profile [1].

In recent years, the number of diseases, injuries and pathologies of the musculoskeletal system (MSS) is growing steadily, which significantly affects the quality of life. Analysis of human gait is subject by many scientific studies. Various diseases and injuries of supporting organs are often accompanied by serious functional disorders of musculoskeletal system, decreased muscle strength and tone, loss of ability to normal movements, which ultimately leads to disability and subsequent disability [2, 3]. The foot is structural segment in musculoskeletal system, which provides it's stomato-motor function, and is integral morphofunctional object that human motor function depends [2]. By exteroceptors located on plantar surface, and it collects information about body mass fluctuations and directs it to the central nervous system (CNS), which will coordinate postural stability [4].

^{*}Corresponding Author: Valentyn Tsapenko, 37, Prosp.Peremohy, Kyiv, Ukraine, 03056, capenko.valik@ukr.net

The foot - is the first, most loaded part of musculoskeletal system, which makes contact with the support, redistributes the reaction force to the higher segments for musculoskeletal system and performs an important spring function, provides stability of the lower limb and adhesion to support surface [5]. There are three main functions of foot:

- spring - the ability to elastic stratification under the action of load and restore its shape after removal of the latter;
- balancing - participation in the regulation of posture and positional activity when standing and walking;
- push (repulsive) - the transfer of acceleration of the total center of mass (TCM) for all body during locomotion [3].

During life, the functional parameters of foot change to one degree or another. First of all, they relate to its spring and repulsive functions. In the case by violations of symmetry for load distribution on foot, as well as by reducing its elastic characteristics - reduced damping properties, which leads to increased shock loads and increased vibration effects on the entire MSS [6]. Currently, longitudinal and transverse flattening of the feet, which can be both independent and in combination with other deformities, is one of the most common orthopedic diseases. According to the WHO, 75% of people have some pathological changes in the feet, which the most common is flat feet (changes in the shape of foot, that is characterized by a decrease in the height of its transverse and longitudinal arches). This deformity is the cause of many serious MSS diseases, which often lead to disability [2, 3].

Analysis of relevant literature sources [6-12] shows the current state of injuries biomechanics and foot deformities. In particular, a significant number of scientific publications aimed at researching the condition by lower extremities of different groups for population and identifying the relationship between foot deformity and other structural disorders of MSS were considered. Researchers note that the problem of early diagnosis of injuries and diseases for feet is relevant in the choice of prevention methods, treatment, orthosis and their effectiveness evaluation. Given that foot bears the main load, the violation of its functions is reflected in entire musculoskeletal system functioning and can lead, in the future, to a number of chronic diseases. The research of human foot in the dynamics (with gradual or sharp variable load on it) is a key factor in the diagnosis for its functional state, which allows you to identify abnormalities and determine the necessary set of treatment measures [6-12]. There are methods for determining the biomechanical properties for foot soft tissues, based on the assessment changes in the pressure values applied from the outside, sufficient to block the arterial vascular bed of tissues, determined by discoloration for skin surface or disappearance of arterioles in blood vessels. However, these methods have a number of limitations, in particular, can't be used in the assessment of gait. During walking, there are additional short-term shock loads of the anterior and posterior shock, in the damping of which may involve various biological media, in particular, in addition to musculoskeletal, fluid blood-lymphatic media play a significant role [6]. Also in scientific publications described the types and variants of gait at various deformations, scoliosis and number of skeleton congenital deformations. The authors of some publications point to the imbalance and lack of synchrony in the

muscles for lower leg and foot, changes in TCM, instability when walking and rapidly progressing pain in various pathologies [11, 12]. However, among the variety of scientific approaches to addressing this issue, the research for distribution the foot load during the full step cycle in dynamics, not fully studied. Known methods don't allow to diagnose functional changes in the foot that occur when the load changes, as well as to determine the individual physiological characteristics of lower extremities, which limits the use of such methods. In addition, in domestic and foreign literature not enough attention is paid to quantitative assessment for parameters of the foot elasticity, while the latter analysis will improve the MSS accuracy diagnosis.

At overloads of arch supporting systems - functions of foot are broken, the motor stereotype as a whole is distorted, there are undesirable redistributions of forces and overloads which are transferred to other parts of MSS therefore there are pathologies. In such cases, the foot works not as an elastic-elastic system, but as an elastic-plastic system, with its inherent residual deformation. The most common cause of the latter is overload associated with functional impairment of foot arches, i.e. recompensation of arches is expressed in a particular injury [6]. Violation for arches formation to the feet occupies 26.4% of all orthopedic pathology and up to 81.5% for all deformities of lower extremities in children [12]. Researches show that in children's these disorders can be partially or completely corrected, while in adulthood - these disorders are extremely difficult to correct, sometimes impossible. It has also been proven that the absence of physiological arches and disturbances for ankle axis joint leads to development of pathological processes in the large joints of lower extremities and spine, and is often the cause of pain [5, 6]. With foot flat-valgus deformity, in addition to muscle weakness and ligaments, the shape and foot bones ratio are disturbed, the reference vector is displaced laterally (to foot outer edge). This changes the nature of gait, is the cause of increasing the dynamic load on the entire musculoskeletal system [2].

Based on this, various foot deformities, in particular flat-valgus, should be considered as primary link in unstable gait formation, which affects the violation of MSS, and leads to various lesions of the latter. The vast majority of modern tool systems are physical rather than linear, which complicates the search for solutions on an elementary basis and sometimes makes it impossible. It's in this statement that modern instrumental analysis develops. For linear systems, the minimum change in the initial state - causes the corresponding changes by its final state. Otherwise, for nonlinear systems, small differences in the initial conditions lead to unpredictable changes in final state. For example, a person undergoing static analysis doesn't know how much and how to change their motor behavior during dynamic analysis [4]. In this regard, morphofunctional diagnosis of the foot is an essential element in the prevention of MSS number disorders, and the applied aspect for analysis of human locomotion, in modern biomedical engineering, is very relevant and promising.

2. Materials and methods

2.1. Formulation of the problem

Clinical analysis of movement and posturological examination are required to objectively assess the distribution of load caused by

the weight of human body on feet and its effect on locomotion. There is baropodometry method, which allows you to objectify the research of biomechanical parameters of foot, taking into account the static and dynamic components. This allows for more in-depth research of locomotions and to detect a certain frequency of identical or pressure similar images, which don't fully correspond to the known metatarsal formula [1-5]. Thus, the research for biomechanics of the lower extremities in norm and at various deformations is necessary and very promising in terms of assessing the state by MSS and forecasting its dynamics.

In order to increase the accuracy for research of biomechanical parameters of foot, it's necessary to take into account the influence of dynamic, namely short-term shock loads caused by body weight on the corresponding phases by the step cycle.

2.2. The foot impact load calculating method

The article task - to identify the initial stages of injuries and foot deformations, is solved by developing a method of calculating the dynamic load taking into account the short-term foot impact.

The foot ability to withstand various loads is due not only to biomechanical perfection, but also the properties of its constituent tissues [2]. Normally, due to vaulted structure of the foot and its spring function, up to 70% of the acceleration is damped and amortized. In normal development of the musculoskeletal system, the load is distributed as follows: through the body of the heel talus, navicular and cuneiform bone, then on the heads of I-III metatarsals, forming an external longitudinal arc (As shown in Figure 1) [3]. The foot biomechanics and its functions in different phases of the step cycle are different. Mitigation of the inertial load during walking and running is carried out by articular ligament difficult complex, which connects the 26 main foot bones, where there are 5 longitudinal bones and the transverse arch. The heel, talus and metatarsal and metatarsal bones form a kind of arch - a spring that can shrink and straighten under the loads action. Body weight is normally evenly distributed on the front and back of the foot. These divisions are connected in a single kinematic chain by inter-articular ligaments, as well as a strong elastic tendon - plantar aponeurosis, which, like a spring, returns to normal position spread out under the load of the foot arch [1-5].

Figure 1: The human foot structure [3]

1 - heel bone; 2 - talus block; 3 - talus; 4 - navicular bone; 5 - medial wedge-shaped bone; 6 - intermediate wedge-shaped bone; 7 - I metatarsal bone; 8 - proximal phalanx; 9 - distal (nail) phalanx; 10 - middle phalanx; 11 - hump V of the metatarsal bone; 12 - cuboid bone; 13 - lateral wedge-shaped bone; 14 - humerus

The gait main functional unit - cycle of the step, that time from the beginning of limb contact with the support to the next same contact with the same limb. The normal locomotor cycle consists of two bipolar and two portable phases. The average step cycle

time, at normal speed, is close to 1s. The step cycle, for each limb, consists of three main periods: the support period, the transfer period and the double support period. Research in the field of biomechanics has shown that the forces applied during movement have vertical and horizontal components. Gait is a complex cyclic movement associated with the repulsion of the body from the support surface and its movement in space. The efforts made are dynamic. Characteristic of normal gait is the constant storage of support on one or two limbs [2].

The basis for any locomotor act is the support interactions, i.e. short-term contact of a MSS certain link with the support, as a result of which there are forces capable of changing the motion center of the body's TCM. Support interactions have all the physical features for shock loads (short duration, significant increase in the modulus of force, etc.), so such interactions can be considered as shock [6].

The algorithm for calculating shock loads is:

- Step cycle registration;
- Determination of biomechanical parameters for step cycle - load values, speed, contact areas of support surfaces, half-step length, etc.;
- Determination for dynamic capacity coefficient of the lower extremities;
- Determination of the dynamic load factor;
- Determination for impact load factor.

2.3. Determination of step cycle biomechanical parameters

During the movement in each step cycle, there are two phases of double and single support. The moment of time t_{fi} of the maximum vertical pressure $P_{v.max}$ is called the forward shock. The time t_{bi} of the rear shock always coincides with the maximum $P_{l.max}$ of longitudinal forces that move the body forward, at this time t_{bi} , the maxima ($P_{v.max} + P_{l.max}$) of the vertical and horizontal forces are summed. Between the moments of time $\Delta t = (t_{bi} - t_{fi})$ of the front and rear shock of the lower extremity there is a damping failure $\Delta P_f = P_{v.min}$, which corresponds for minimum vertical pressure. When the overall center of gravity rises higher, the pressure on the support is directed forward, replaced by the pressure directed backwards, i.e. the braking is replaced by a push. In healthy people, the step reference period is $t_{rp} = 0,64 \pm 0,016$ s, the transfer period $t_{tp} = 0,36 \pm 0,014$ s, the two-support period $t_{rtp} = 0,135 \pm 0,010$ s. The duration of support time on the right and left foot usually differs by $\pm 5\%$ and is [2]:

$$\Delta t_{tp} = (24-29)\% \cdot t_k \quad (1)$$

where t_k - step time.

Given the different pace, these rates are estimated as a percentage for entire step cycle: the period of rolling through the foot is equal to [2]:

$$\Delta t_r = (45-51)\% \cdot t_k \quad (2)$$

The method of baropodometry was used in the research. The platform consists of 4 active modules, measuring 0.4×0.4 m and 4 passive. 6400 sensors are installed in each active module (the total number of sensors on the platform is 25600) [1]. The platform works in two modes: static and dynamic.

Baropodometry of static position determines the distribution of load zones, outlines the perimeter of the support polygon, fixes the centers for foot position and the projection of TCM and its displacement, calculates the percentage of support surface and pressure force, including limb overload or pelvic rotation. Static analysis is considered as a geometric model that relates basic biomechanical parameters, correlating with the information obtained from the morphology of the sole (podocontourmetry), and with the reflection for foot pressure obtained in the dynamic analysis. Quantitative values of pressure imprints, detected after the research and presented in the section of static analysis, allow you to notice any possible asymmetry or deviation from the physiological state. The most important of these are divided into "load values" (correlated mainly with pressure information) and "offset values" (correlated mainly with spatial information) - they are interrelated [6].

Baropodometry in the dynamics shows how the pressure is distributed during the rolling to each foot. The point of landing, contact and shock normally have a clear sequence, speed and strength. The graphical representation of the movement can clearly track the stability of the joints, lateral or medial deviations of movement. In the process of analysis, cycles of steps with time characteristics of mono-support and double support are recorded. Elongation of the foot with dynamic support, its expansion in the anterior part during movement are determined. The full step cycle is analyzed for three prints, and a half-step for two. Having a complete step cycle is always a more informative parameter than single prints. When walking, there can also be a supporting mid-foot polygon (As shown in Figure 4), i.e. the moment at which the body transfers the load from one limb to another during the double support. This parameter is crucial in the kinematic reconstruction of stability disorders, which can be caused by incorrect contact, because it allows to detect the interaction of possible stability disorders [4].

Figure 4: Supporting mid-foot polygon [4]

The research of the load distribution on foot plantar surface. According to formula above, determine the dynamic capacity coefficient q (6). After the corresponding calculations it was obtained: for 40% of the group the left lower extremity has the maximum period of support, in the rest of the group - the right. Further calculations were performed for a larger group, i.e. on the left support.

3. Results and discussions

In order to analyze the distribution of dynamic load on the support surface, let's introduce the coefficient of dynamic load K_{dl} [2]:

$$K_{dl} = P_i \cdot S_i \cdot t_i \quad (8)$$

where P_i – the value of the load on the i -th characteristic of the cycle for foot step (the period of push, roll and landing), kg/m^2 ;

S_i - characteristics area, m^2 ;

t_i - duration of the characteristic, s .

Impact is a load that is applied in a very short period of time. For example, the shock load occurs when one body falls on another or when the pressure between the bodies in question changes rapidly. It should be borne in mind that if considered a body with a certain mass m , such as a weight of 20 kg , the weight of the weight will not change before, after or at the time of fall. This statement is true only when it comes to gravitational mass, but a thorough world research of the phenomena shows that any body also has an inert mass. Researches show that the inertial mass is equal to the gravitational mass, and when it comes to shock loads, they are created not by gravitational but by inert mass. From the general course of physics, the term "load" is not used, but the concept of "force" is used. In this case, all forces can be divided into external and internal. In the course of theoretical mechanics, the theory of resistance of materials, the theory of elasticity, the theory of strength, etc. external forces acting on a particular structure are considered as loads, and internal forces - as stress. It's assumed that the sum of external forces is equal to the sum of internal forces, this ultimately allows you to make an equilibrium equation for the selected system [2, 6]. In this research considered the human body with mass m , as a concentrated load Q_{st} , which according to Newton's second law is calculated:

$$Q_{st} = m \cdot g \quad (9)$$

where m – body weight, kg ;

g – acceleration of gravity.

Due to the support interaction of body weight with foot, in the latter there are certain ratios of elastic forces - the internal force field, which counteracts the occurrence of plastic deformations by support caused for body weight. If the support conditions change (for example, when changing posture), then the configuration for the force field of elastic forces in the considered system changes accordingly. In this case, if a person doesn't move, i.e. the speed of its movement relative to the considered frame of reference is "0", then his body still creates a load - static. Here, a human foot is considered as a support that acts with force equal in value to the reference force of the human body F (load caused by the mass of the body applied to the support) and opposite in direction, such a force is called the support reaction R_d . When $R_d = F$ – the system is in equilibrium. After the start of motion with a certain acceleration a there is a vertical force of inertia directed opposite to the acceleration. Accordingly, if the inertia force is directed downwards, the load caused by the body mass on the resistance

increases, because under the influence of acceleration, the static load Q_{st} is replaced by dynamic Q_d :

$$Q_d = Q_{st} \cdot \frac{a}{g} \quad (10)$$

Relation a/g is a measure of mechanical overload, which determines the change in physical condition of the body. If the load is applied instantly - the reference force will be the maximum value, because the body is mass m , at a certain point in time t will reach a fairly high speed v , therefore, the calculations must take into account the gravitational, inert mass of the body and the inert mass of the system (body + support). Therefore, when we consider the types of loads on the human foot, it is necessary to consider shock loads as one of dynamic loads types, which differ from static ones in that the maximum stresses should take into account the forces of inertia.

If we consider the body of person with mass m as a physical body that creates a load, and his foot - as a body that receives this load with the occurrence of certain stresses, then the interaction of the body with the foot - the speed of gravity of both bodies, according to accepted frame of reference, do not change. This allows us to consider the loads and stresses caused by them as those that are due only to the gravitational interaction. The foot as a supporting structure is the first to perceive the shock pulse p of the reference reaction, and the further nature of the interaction with the environment directly depends on its functional capabilities.

$$p = m \cdot v \quad (11)$$

where v – speed of movement n -th phase of the step cycle, m/s .

In this research, we consider a rectilinear (translational) motion, i.e. one for the description of which it's sufficient to consider the movement for only one material point, which in this case coincides with the body gravity center. The method of calculating the coefficient of dynamic load on the foot (8) is described above. We introduce the coefficient K_{st} , which takes into account the total area of foot support S and the time of its contact t with the surface:

$$K_{st} = S \cdot t \quad (12)$$

The coefficient value K_{st} will be maximum at the maximum area of foot support, taking into account the period of support. The total amount of foot support reactions R_d , which create shock loads will be equal to the value of effective impact force Q_{shl} body weight. Based on this, it's fair to say:

$$P = Q_{shl} = R_d \quad (13)$$

where $P = \sum P_i$ – total value of the foot load.

And from equation (12) we obtain the coefficient K_{shl} shock load for a certain phase for step cycle, which can be written as:

$$K_{shl} = K_{st} \cdot R_d \quad (14)$$

Under normal conditions, the foot is exposed to elastic deformations, i.e. it can be considered as an elastic system with one degree of freedom. Then, theoretically, if known the time t during which the pulse will be transmitted from one body to another, the impact force can be calculated by the formula:

$$Q_{shl} = \frac{P}{t} \quad (15)$$

However, in practice it's very difficult to determine the pulse transmission time, because it depends on many different factors and can vary from microseconds to seconds. Therefore, to accurately determine the value of time, and hence the impact force is quite difficult.

To solve this problem, accept the following assumptions:

- in this research, it will consider the foot as an elastic system with one freedom degree. That is, we believe that all the deformities of the foot will be in the area of elastic, restored later.
- deformations of the considered element for design from loadings extend on all length of an element, obey Hooke's law and are proportional to deformations arising at static application of loading from the same body and in the same place.
- the proportionality of dynamic and static deformations is determined by dynamic coefficient q (6).

Given this, formula (14) will look like:

$$Q_{shl} = q \cdot \frac{m \cdot v}{t} \quad (16)$$

Taking into account expression (6) and carrying out the transformation, formula (16) is written as follows:

$$Q_{shl} = \frac{P \cdot v}{t} \quad (17)$$

where P - the total value of the load on the foot.

Given expression (13), it can be write the formula for calculating the coefficient of shock loads as:

$$K_{shl} = S \cdot P \cdot v \quad (18)$$

Researched for the coefficient of shock loads for above group of subjects. The calculation was performed by left support. Together with the calculation for this coefficient determined the length of the half-step l . Figure 5 shows a graph of the coefficient of foot impact loads K_{shl} on the length of the half-step l .

The half-step l calculated as the distance from the center of heel in the first phase of the step cycle to the center of heel to the same foot in the next phase, m . The graph shows that the maximum value of shock loads coefficient (0,584) corresponds to the maximum value of the half-step length (0,7 m), and therefore we can conclude

that the greater for half-step length - than the greater the coefficient of foot shock loads.

Figure 5: Graph for dependence of the coefficient of foot shock loads from the half-step length

4. Conclusions

The problem of early diagnosis for injuries and deformities the feet is relevant when choosing prevention methods, treatment, orthosis and evaluation for their effectiveness. An important design feature of the foot is its vaulted structure, which provides spring, balancing and repulsive functions. The foot, under normal conditions, is exposed to elastic deformations, i.e. it can be considered as an elastic system with one degree of freedom. It should be emphasized that the human musculoskeletal system is quite complex, but the foot as a supporting structure and part of this system is first to perceive the shock impulse of the support reaction, and its functionality directly affects the further nature for interaction with the environment. The supporting foot properties haven't been fully researched - to increase the accuracy of their evaluation methods, it's necessary to take into account the dynamic influence, namely short-term shock loads, on the step cycle relevant phases.

Proposed new method of analysis for stato-dynamic load, which allows to estimate dynamic and shock foot loads and is reduced to the determination for corresponding coefficients. It's established that the maximum contact per unit time has front part (repulsion phase), then the rear part (landing phase) and the smallest - the middle foot part (rolling phase), the greater the speed and stride length, the greater the coefficient of shock loads, and their peak on the anterior and posterior departments, therefore, these areas need special attention when choosing methods of prevention, treatment and orthosis.

The practical significance for obtained results is to improve the existing methods of researching foot biomechanical parameters, by comprehensively assessing the features of standing and walking, step cycle and support properties. Considered method of researching the functional properties for lower extremities, and in the future, will be consistently improved and expand the range of its application. In particular, in order to assess the dynamic stresses arising in the feet caused by shock loads, additional researches will be conducted using the measurement by force plate, which will increase the effectiveness of prevention, treatment and orthosis of MSS segments.

River flow

Impacts

ABSTRACT

The behavior of rivers' hydrology and flow under changing climate has been an objective of interest for long time. In this study the impacts of climate change on streamflow of the Arkansas River will be investigated. The paper is an extension of work originally presented in ASET conference in Dubai. The Arkansas River is a crucial element in the economy of the Colorado state in the USA. It is a vital transportation channel and main source of water for irrigated agriculture. In order to understand the direction and magnitude of climate change, the changes in the monthly flow regimes of the Arkansas River were projected using two future climate scenarios. The projections extend over 100 years (2000 – 2100). The projections were carried out in the period from April to September because this is the period of the river's significant runoff. For better presentation the monthly flows were aggregated and presented on decadal time scale. Project stream flow is simulated using a neural network that was developed to autonomously model the relationship between different flow levels and the resultant changes in temperature and precipitation. In general, the projections depict a rise in the magnitude of the flow in the river. In general the increases concurred with the patterns of temperature and precipitation projected for the region. Noticeably, the high temperatures cause the precipitation to melt earlier shifting the peak flow to April instead of June. Statistical analysis show that in the future the current levels of flow would be surpassed more frequently. The probability of exceedance fluctuates between from month to month – reaching its peak in April-July; before retreating to a very low level in August and becoming almost negligible in September. Overall, the results reveal profound implications for regional water resource planning and management.

1. Introduction

The Arkansas River is a crucial element in the economy of the state of Colorado, in the western United States. It is a vital transportation channel and main source of water for irrigated agriculture. Water sources for the river mainly from snowmelt.

Snow melt is a critical component of the water cycle in the American West, providing the region with at least 50% of its annual runoff, and up to 80% in some years. Concerns are growing regarding the impacts the altered climate might have on snowpack and the region's water cycle overall. A few studies projected the region to have profound changes in minimum winter temperatures, summer average temperatures, snowfall, snow-melt, and growing season rainfall quantities [1]-[5]. Several other studies have

reported that spring and early summer temperatures are expected to increase while the quantity of snowpack in spring is expected to decrease [6]-[8]. There are other several earlier studies of snowmelt dominated systems show similar seasonal shifts in snowmelt runoff as a result of warmer temperatures and a shorter snow accumulation period [8]-[11].

If the changes in climate take place as projected, it is expected to have profound impacts on the hydrology of the Arkansas River and hence the economy of the region. Many studies, using historical data analyses, have explored the impacts of climate change on water in this region where water is already under stress [12]-[19]. The outcome of these studies reported that, even though, the direction and magnitude of change in climate is well documented (increase in temperature) but there is no consensus on the direction and magnitude of the impacts on the region. And this attributed to uncertainty regarding the changes in precipitation's

^{*}Corresponding Author: Elgaali, P.O. Box: 15825, Dubai, UAE, 971 552493085, eelgaali@hct.ac.ae

patterns under warmer climate. But, precipitation is the main driving factor of the changes in streamflow. Almost all of the studies conducted in this region, have reported that snow is expected to melt early shifting the peak runoff and the growing season to take place earlier. But none of them reported increases in streamflow. However, the changes in precipitation regimes are expected to cause the snowpack to decrease and/or to melt (shift) earlier. Therefore, streamflow is expected to decrease and the peak emanates earlier shifting the growing season towards winter season [6], [13], [16]. Some studies on the region, projected a reduction in streamflow up to 30% below the historical recorded flow [18]. More recent studies using data sets extracted from GCMs support this result projecting a reduction in streamflow ranges between 10 – 30% by the end of the 21st century [6], [13]-[14]. The only increase in streamflow resulted from increase in precipitation was reported by Groisman and others [20].

It is noticeable, from the outcome of all these studies that there is no consensus on the magnitude and direction of the change in the precipitation and hence the river flow under the changing climatic conditions. This may be attributed to the nature of the climate and hydrologic models used (coarse spatial and temporal resolution). The coarse resolution bounds the general circulation models (GCMs) to reproduce a similarly complex spatial environment that simulates the actual precipitation. Besides, the discrepancies in the precipitation projections are larger than the ones in the temperature projections [21]-[23].

Scale is crucial for climate and hydrologic modeling. It is reported that the signal of climate change on monthly patterns of runoff is stronger than the annual ones [23], [24]. Projections at finer scales is necessary to better evaluate the impacts the changing climate might have on the hydrology in the region [25]. Therefore, in this research, streamflow is linked to climate change scenarios on a monthly scale and aggregated to annual and decadal scale.

Series of climate parameters (scenarios) have been projected to simulate the changes in climate in the future. Most of these scenarios were developed assuming equilibrium (change in climate caused by jumps in CO₂ levels in the atmosphere sometime in the future). In fact, climate is expected to have linear trend of change (transient) following the linear trend of CO₂ on the earth [26], [27]. Even though, transient scenarios have not been widely used in studies of climate change. As such, it is necessary to explore their impact, as:

- Transient studies provide deeper insight on trends in climatic change and annual variability;
- Transient projections can indicate the potential rate of change, which is crucial in determining how to respond and adapt to that change, and;
- Transient simulations may give a more accurate picture of the likelihood of when certain critical thresholds will be crossed [27].

This research aims to demonstrate how transient scenarios are better able to evaluate the implications the changing climate might have on river flow at scale. These findings can be particularly

useful in supporting or facilitating more informed and higher quality decision-making for water planning and management.

2. Description of the Study Area

The subject of this study is the Arkansas River Basin in Colorado which is enclosed by the Rocky Mountains to the west and Kansas to the east and expanding towards New Mexico and Oklahoma to the south. (Figure 1), the surface area of the basin is approximately 72,742 km² (28,415 square miles) and accounts for about 27% of the land area of the state of Colorado. The river's headwaters can be found at over 3,050m (10,000 feet) above sea level, in the vicinity of Leadville, CO. From there, its elevation drops rapidly as the river flows out of the mountains near Pueblo, CO and continues eastward towards the border with Kansas border, near the town of Holly, where the elevation drops to roughly 1,036 m (3,400 feet).

The basin sees a wide range of temperatures and precipitation due to variations in topography. The temperature can see average annual lows of about 2°C at the basin's highest point in the mountains and can reach average highs of about 12°C in the lower valley. Seasonal variations are also significant, illustrated by the average frost free season (0°C) ranging from a low of 85 days at Leadville to a high of 167 days at Canon City.

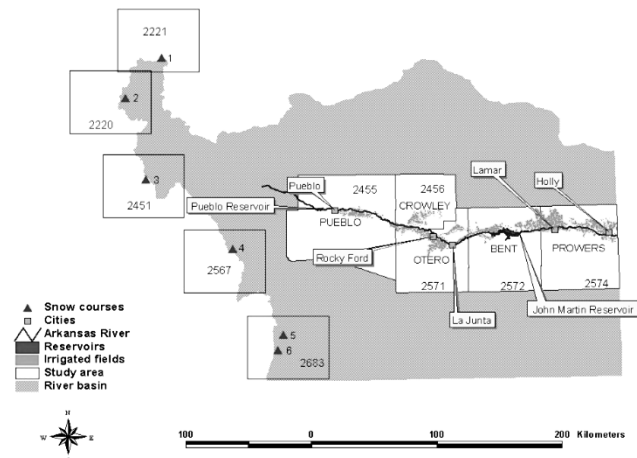

Figure 1: Features of the study area in the Arkansas River Basin, Colorado

Precipitation also demonstrates significant variability throughout the year, ranging from 229-305 mm annually in the middle and eastern parts of the basin, to 406-508 mm in the center and east, to a range of 406-508 mm in the west, and as much as 1143 mm at the highest elevations in the mountains. At these heights, much of the precipitation manifests as snow, the runoff of which accounts for the bulk of the region's annual water supply. Consequently, the size of the water supply is dependent on the volume of winter snowpack and can shift from year to year. However, in general, on average, over 60% of the annual runoff takes place in late spring and mid-summer between April and July, with a further 20% occurring in later summer and early autumn between August and October [28].

3. Data

The underlying data for this study is in two parts: (1) historical climate scenarios and (2) future climate scenarios. It was sourced

from the Vegetation-Ecosystem Modeling and Analysis Project (VEMAP) [29] which collected extensive climate data for the contiguous United States and includes historical data dating back to 1895 and up to 1993, supplemented by projections from two GCM-based scenario models covering the period from 1994-2099.

The historical scenarios were based on data records of varying length from 1,200 stations for the 105-year period between 1895 to 2000 as well as shorter records from approx. 6,000 to 8,000 stations for the 50-year period between 1951 to 2000. Both GCM models, the HAD model and the CCC model, further output climate scenarios with the underlying assumption that carbon dioxide concentrations are progressively increasing at a rate of 1% every year (transient). The VEMAP divided the continental US into a grid with $0.5^\circ \times 0.5^\circ$ cells and used these to generate scenarios that would demonstrate the impact of factors such as topography and local ecosystems on climate [29]. The project sponsor, the National Center for Atmospheric Research (NCAR), used a downscaling technique, spatial interpolation to topographically adjust both the historical and projected climate data to fit the small grid cells. The downscaling process took into account the impact of local topography on climate parameters. Figure 2 shows adjusted projections (downscaled) from both models as well as the mean ± 1 standard deviation for each parameter.

Figure 2: Historical and the future scenarios of Precipitation and Temperature

The historical data, sourced from the U.S. Geological Survey (USGS) [30], captures flow levels for the Arkansas River near Pueblo, on a monthly basis between 1900 and 2000. Figure 3 shows the average monthly distribution of the river flow with data collected over 30 years.

As shown in Figure 1, climate data (precipitation & temperature) was collected from five snow courses (grid cells) in the Rocky Mountains a sample which represent overall runoff in the region. Each individual cell contains a minimum of one course upon which runoff forecasts were based. Since the accuracy of the model's simulations depends heavily on the accuracy of the input data as well as the temporal and spatial scale, the selected snow courses were vetted to ensure accurate and reliable records that reflect the natural runoff and correlated highly snowmelt levels across the entirety of the region [28]. The selected courses, as well as their grid cell number are listed in the adjacent table below (Table 1).

Figure 3: Seasonal Cycle of the Arkansas River at Pueblo

Table 1: Characteristics of Snow Courses

Station	Latitude (deg)	Longitude (deg)	Elevation (m)	Cell #

South Colony	37.97	105.53	3,294	2567
Whiskey Creek	37.22	105.12	3,117	2683

4. Methods

In this paper, in order to study the changes in the river flow that would accompany any climatic changes in the future, we used climate scenarios (precipitation and temperature) extracted from two General Circulation Models (GCM). Namely, the Hadley Centre for Climate Prediction and Research (HAD) and the Canadian Climate Centre (CCC). The data from these two GCMs is of transient nature (gradual change) and high spatial and temporal resolution. To account for spatial variability, the climate data was scaled-down and then used to quantify the impacts the climate change might have on the monthly flows of the river (Arkansas River). The paper focused to explore the changes in streamflow during the period of April-September, because this is

the growing season in the region, and the time during which the effective runoff is usually generated. The monthly flow in the river was simulated using artificial neural network (ANN). The neural network models have been proved to be capable to transform minimum number of inputs into an output [31] - [33]. The neural network model was used for the minimum number of the input data sets it requires. The model was calibrated and validated using 100-years of historical data records. To account for the extrapolation, the historical data was reinforced by extreme events that supposed to resemble the climate conditions under global warming. The ANN model was then used to simulate the river flow under global warming conditions. The output (simulations) from both models (GCM and ANN) are compared to historical records (baseline) to estimate the quantity and extent of the change.

4.1. Modeling Streamflow

The model developed can be described as feedforward artificial neural network (ANN). It is three-layer network; in the middle layer there is a function that map the relationship between the inputs in the first layer (precipitation (PPTa) and temperature (T)) and the outputs in the last layer (streamflow (Qr)). The ANN is well formulated in the following form:

$$Q_r(t) = f(PPTa, T) \quad (1)$$

Here, Qr represents the average monthly streamflow whereas PPTa represents precipitation (accumulated from October of the preceding year, up to each individual month of the year after). To illustrate, the value of PPTa in April would be equal to the cumulative levels of snowpack between October and April. The variable T, meanwhile, represents the average temperature (calculated between April and each individual month in the model). Again, to illustrate, the value of T for May is equal to the average temperature between April and May. For the month of April itself, we substituted the average March temperature. Accumulating precipitation and temperature was found to contain stronger signals of climate variability. The input data to the ANN was normalized to fall in the range (-1, 1). Normalization is required to remove geometrical biases and equally distribute importance of each input.

4.2. Model Testing and Validation

Data records of 100 years (1900 -2000) were used in training, validating, and testing the neural network. Sixty years of data records (1900-1960) were used for model's training, 14 years (1961-1975) were used for validation, and 24 years (1976-2000) were used for testing.

The developed neural network was found favorably capable to simulate the river flow (output) when the precipitation and temperature were used as inputs. The parameters shown in Table 2 summarize the validity of the model. The correlation coefficient (R) is usually used to show the degree of connection between two variables. The values of R range from zero as minimal to one as optimal (0, 1). The Root Mean Square Error (RMSE) is used to determine the magnitude of departure (residual variance) of simulated values from measured ones; the zero value indicates the least magnitude of departure (optimal value).

However, the values of the presented parameters (R and RMSE) document the high correlation between the measured and predicted values and hence the validity of the developed model.

Table 2: Summary of the Model Validation and Testing

Month	Training		Testing	
	<u>R</u>	<u>RMSE</u>	<u>R</u>	<u>RMSE</u>
April	0.634	0.17	0.562	0.24
May	0.790	0.10	0.770	0.18
June	0.863	0.11	0.847	0.15
July	0.899	0.06	0.740	0.13
August	0.852	0.06	0.781	0.12
September	0.904	0.07	0.769	0.17

5. Results and Discussion

5.1. Climatic changes

To determine the directionality of the climate change in the region, the main features of the climate scenarios generated from the two GCMs are presented. For better presentation the climate scenarios were aggregated into decadal monthly mean.

Fig. 4 shows the changes in the average monthly temperatures under the two scenarios (HAD and the CCC). The GCMs predicted slight increase in temperature (the region is projected to be warmer). There is a very clear gradual increase in temperature. The change in temperatures during the winter (Dec – Feb) is predicted to be comparatively higher than in the summer (June – August). The changes in temperature look high when compared to the very low historical series of temperatures in winter.

During the focus period (April–September) the temperature average is predicted to increase by 5°C in the 2090s, with a growth rate of 0.45°C every decade. Generally, the 2090s is predicted to be the warmest decade. The figure shows that the CCC scenario predicted higher temperatures in the region compared to the HAD scenario. However, the temperature projections, generated by both scenarios, are similar in trend of change.

Fig. 5 shows the changes in monthly precipitation in decades. It is shown that the HAD scenario predicted large and sudden changes in the average monthly precipitation. Despite the variation, the figure shows a clear pattern in the decadal mean. The figure shows an increase in the decadal mean from the 2010s to 2030s. The increase was gradual at a rate of 1.4% per decade. The 2040s and 2050s noticeably experienced a drop in the decadal mean. The drop was gradual and rapid at a rate of 1.4% per decade. Then a gradual increase took place again. There was rapid and gradual increase in the decadal mean from 2060s to the 2090s with a growth rate of 2.2% every decade. The projected drop in precipitation could be attributed to changes in natural, large-scale features of the climate: the El Niño Southern Oscillation (ENSO), El Niño, and La Niña [20]-[24].

In general, under the HAD scenario, the increase of the precipitation above the historical base line is expected to be of magnitude of 36% in the spring and of 25% in the summer. On the other hand, it is shown that the CCC scenario predicts a drier

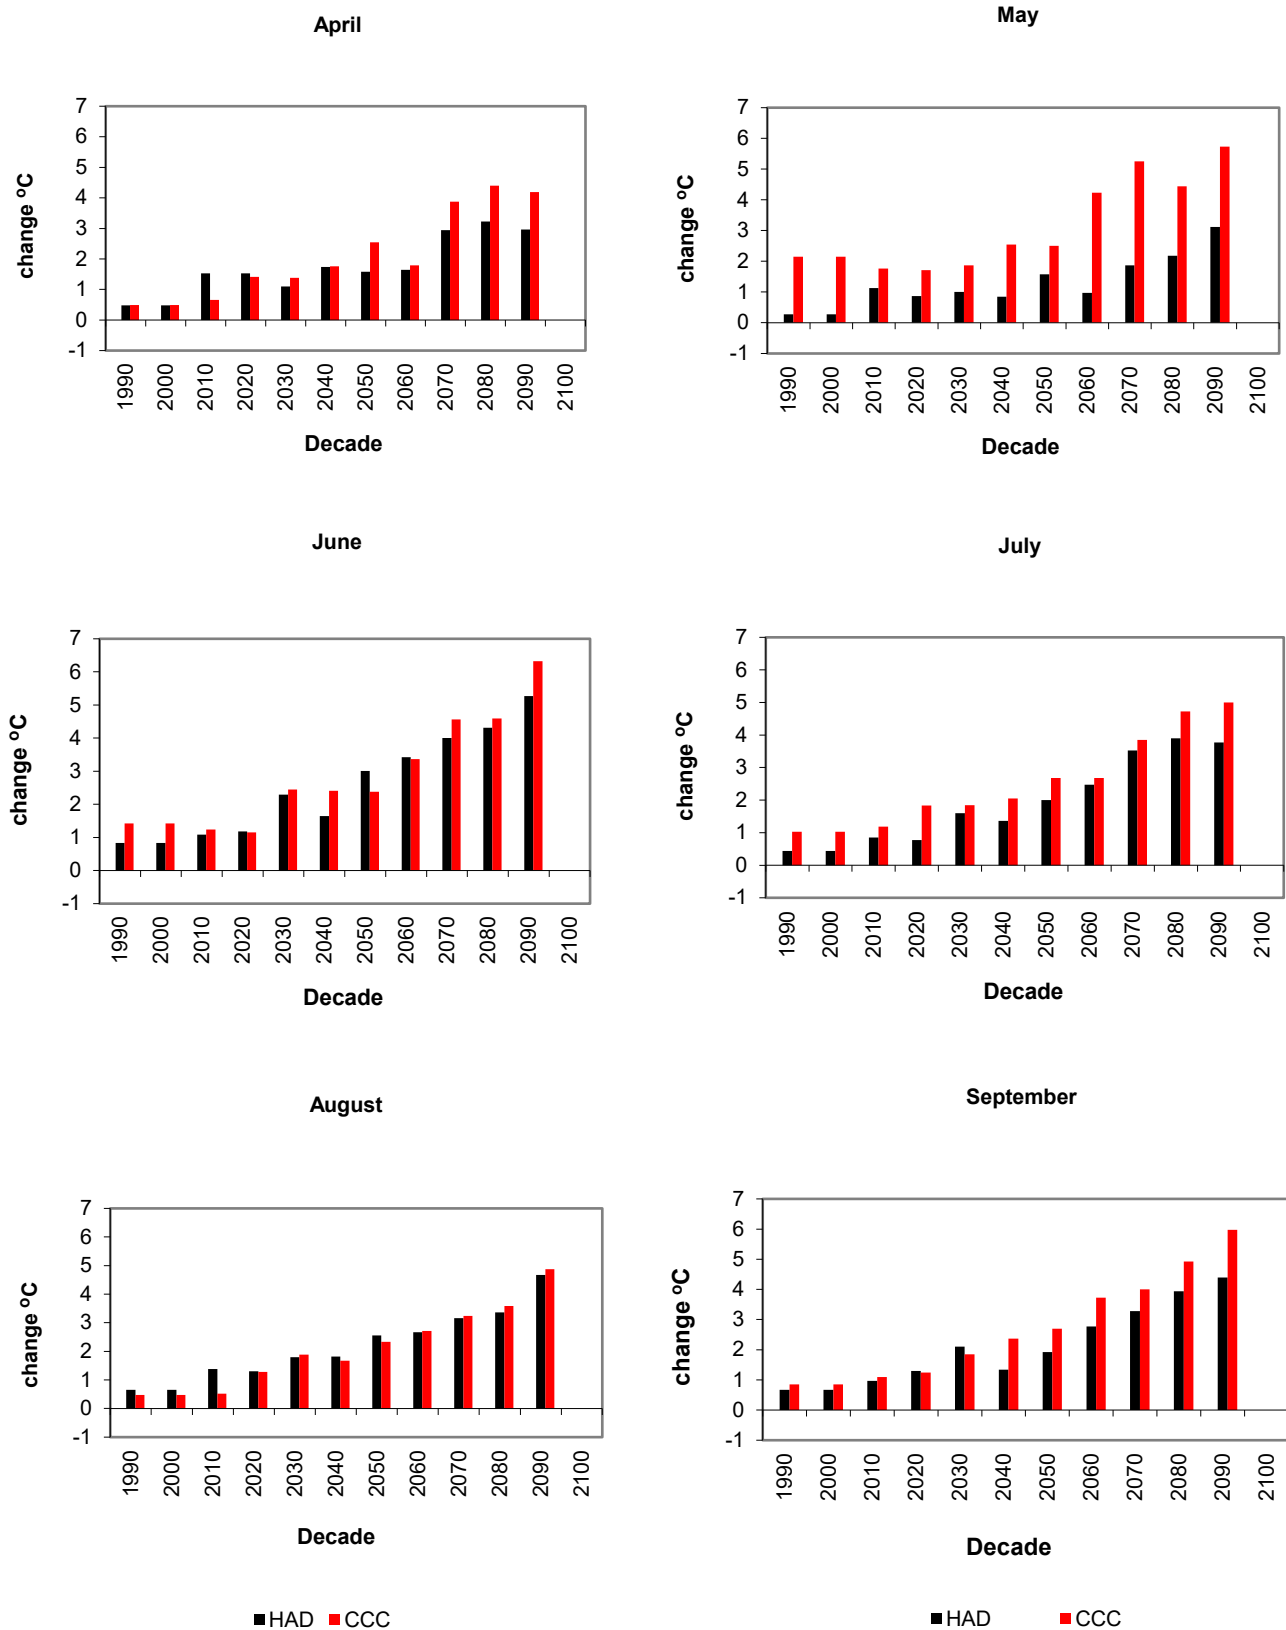

Figure 4: Departures, form historical distribution, of temperature projections from the GCMs: HAD/CCC

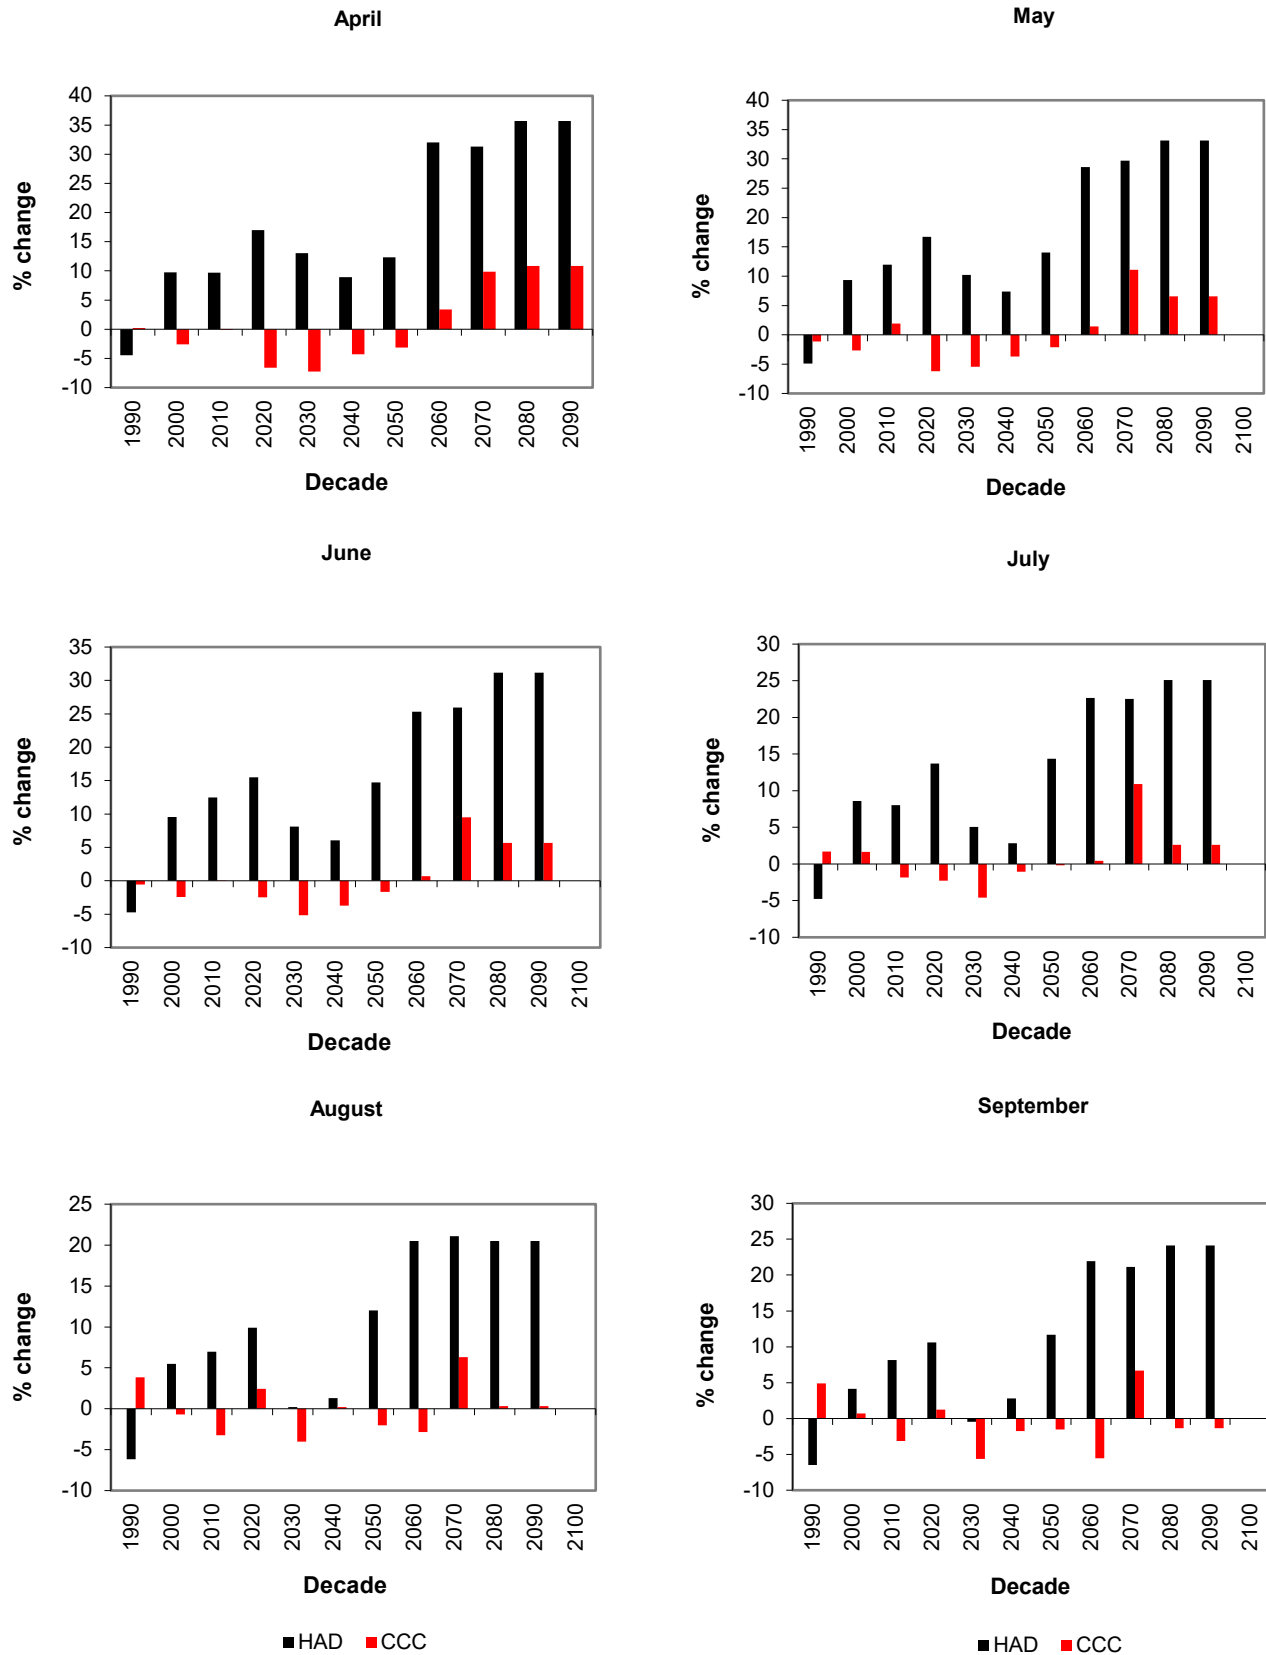

Figure 5: Departures from historical distribution of precipitation projections from the GCMs: HAD/CCC

climate for the region. The projections of the CCC show no clear departure from the historical levels except for the 2080s where a the region was projected to have significant increase (9% above the baseline). Worth to mention, the driest climate is expected during the 2040s with a departure of 7%, below the historical levels, in April, 4% in August, and 47% in October. However, the CCC tends to project precipitation patterns with no clear trend and less variability compared to the HAD. Generally, the two scenarios, show poor similarity in the trend and the extent of change in the precipitation projections.

5.2. Impacts on Streamflow

Figure 6 shows the projections of streamflow. The projections are compared to the historical flow distribution. In spring season, under the HAD scenario, driven by the projected increases in precipitation shown in Figure 5, the results show a large increases in future monthly streamflow. Compared to historical records, the average monthly streamflow increased by 87% for the 2030s and 2050s. The increase jumped to an average of 200% for the 2070s, 2080s, and 2090s. In summer, the increases are projected to be less ranging from 39% for the 2030s to 74% for 2090s. In the fall, dampened by the increase in temperature, the increase in streamflow dropped to 5% in 2030s and to 15 % in 2090s. In general the results show that the largest departures (increases) in flow occur in late spring (April) through early summer (June). This is attributed to the early melting of snow in the mountains. The combined effect of high temperatures and increase in winter snow leads to early snowmelt. However, as a result of change in climate, the peak flow is expected to occur in April rather than June.

The CCC scenario projects a drier climate than the HAD one. Driven by the projected decreases in precipitation shown in Figure 5, the results show that, for 2030s and 2050s, the future monthly streamflow experiences a very slight decrease (5%) in the summer and negligible change in the spring and the fall. For the 2070s and 2090s, the results show a considerable increase (65%) in the spring and negligible change in the fall. The fluctuations (decreases and increases) in projections of the streamflow are attributed to the annual and decadal variability in the projected changes in climate. The results presented here is widely supported by other several earlier studies conducted on the region [7], [9], [13]-[15].

Figure 7 shows the frequency analysis results of the monthly flow during the focus period (April – September). The results are presented in terms of flow duration curves (FDC). In general, FDC are used to depict the percentage of time the flow in the future exceeds the current levels of flow (historical). Under the CCC scenario the percent of exceedance is almost nil for all months. Under the HAD scenario the percent of exceedance is high for all months (April – September). The flow duration curve falls above the historical (baseline) curve, indicating that the river flow in the future exceeds the current flow value (historical). The probability of exceedance differs from month to month; it is relatively high in the months of April to July and low in August. In September the probability of exceedance almost nil because the two flow curves (historical and future) look similar and almost coincide. The variability in the projected flow is greater in April-July, indicated by the steep flow curves, and stable in August and September inferred by the gentle flow curves.

Figure 6: Historical and projected streamflow of the Arkansas River

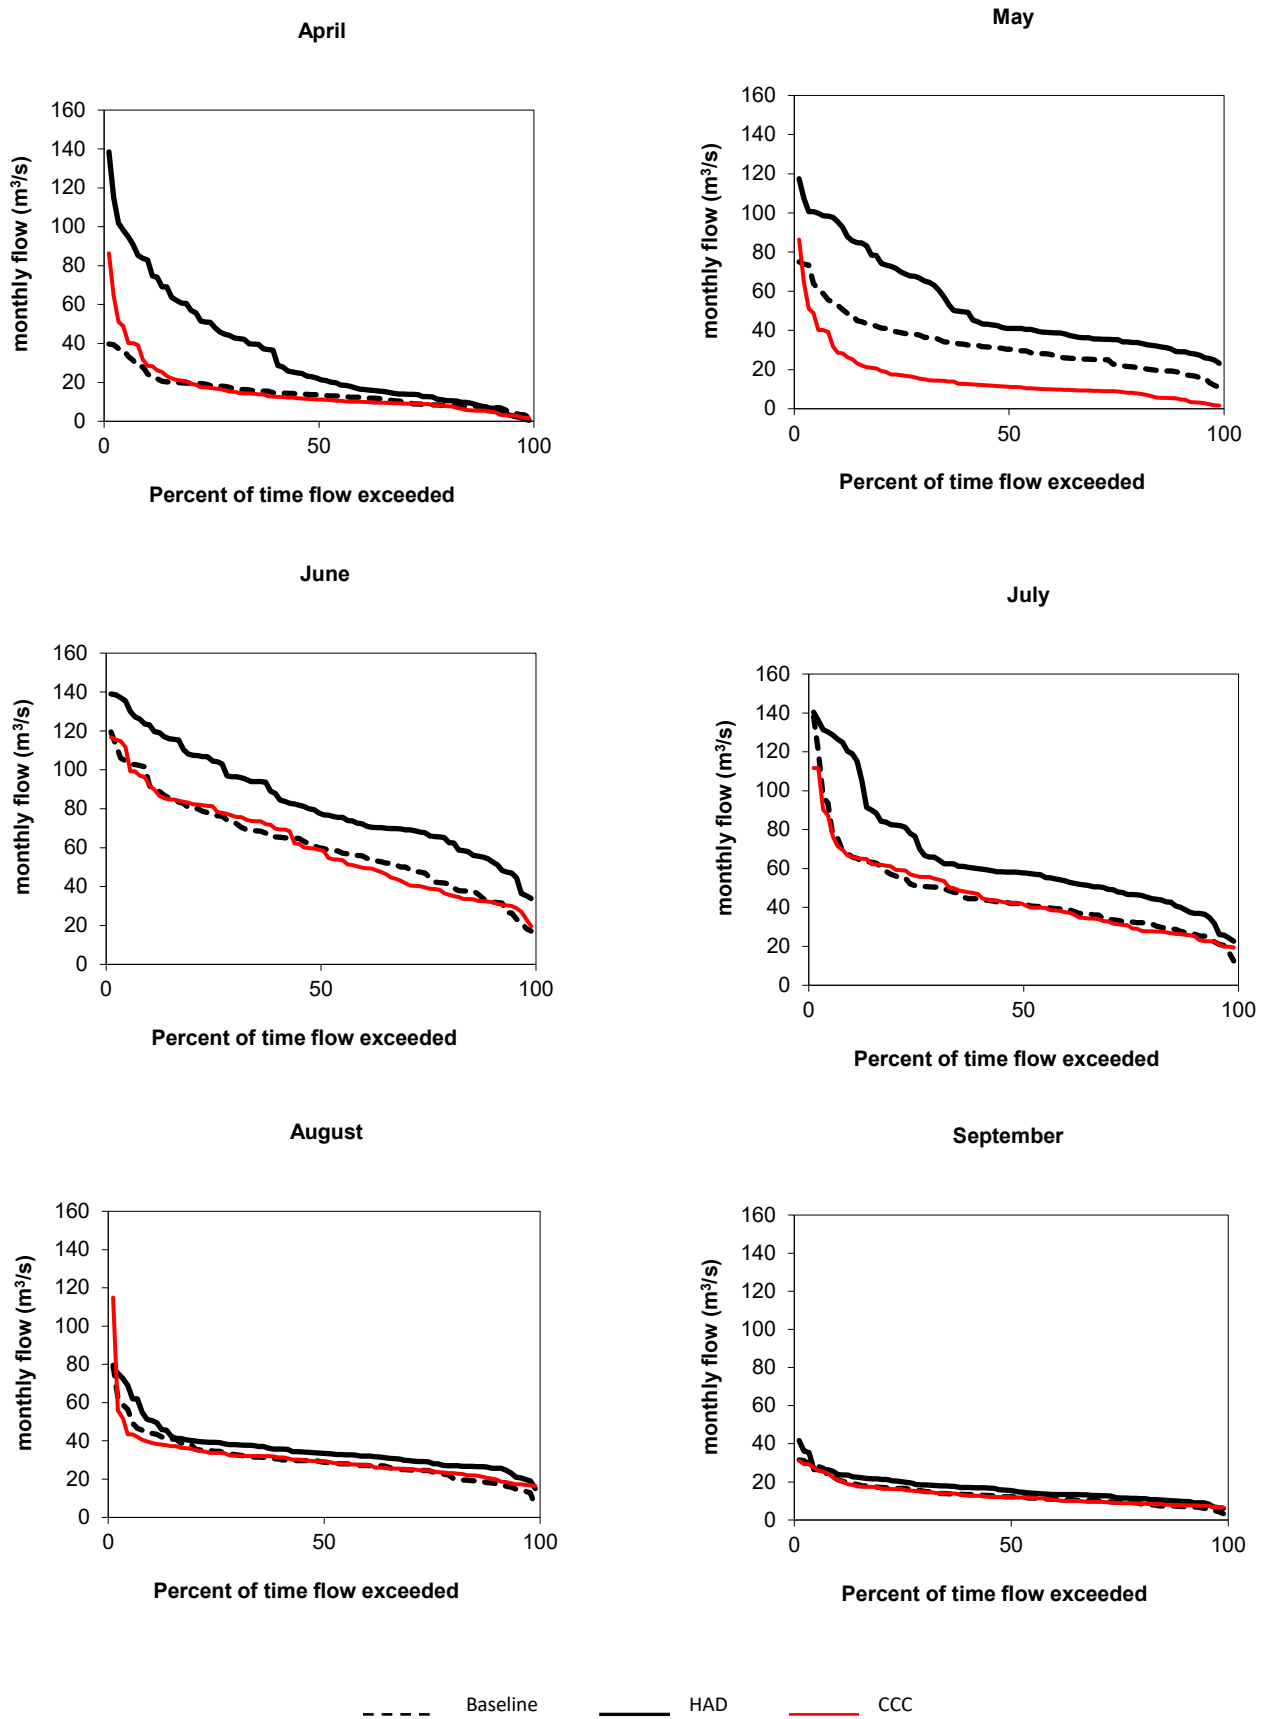

Figure 7: Flow duration curves for monthly flow

This study investigated the influence of different climate phenomenon, caused by climate change, on the flow levels of the Arkansas River in USA. In order to carry out the study, time series of climate data in the future (scenarios) were extracted from two GCMs (CCC and HAD), and then plugged in a hydrologic model (ANN) to generate time series of flow. While the scenarios, produced by both models, agreed that the temperatures were likely to increase, they differed on the directionality of the change in terms of precipitation levels.

However, under the HAD-generated scenario, there is expected to be a relative increase in precipitation, resulting in increased wetness, while the CCC-generated scenario is comparatively dry and demonstrates higher variability. This variability can be attributed to annual, as well as decadal, shifts in expected climatic changes.

The results of this investigation suggest that, under the range of climate conditions studied, river flow processes are strong indicators of how climate change is impacting temperature and precipitation levels in the region. The HAD scenario in particular suggests that present flow levels are likely to be regularly exceeded in the future, especially during the peak April-July period. It further suggests that any increase in springtime flow is likely to be sizeable enough to compensate for attendant decreases in summertime flow and they further demonstrate that the historical peak flow, which used to begin in June has shifted to begin in April, extending the period of high flow levels. These results also align well with the results of other studies that explore the expected environmental effects of rising temperatures on local ecosystems in the western parts of the US [12]-[15].

The Arkansas River Basin can be considered one of the most vulnerable regions in the country when it comes to climate change. If, moving forward, precipitation levels match the projections, in terms of both magnitude and timing, they can be expected to have a significant impact that pose challenge to the water planners and managers in the region.

Conflict of Interest

No conflict of interest in publishing this paper.

Acknowledgment

The authors would like to thank VEMAP for providing the climate data.

ABSTRACT

The literature shows a growing interest in taking into account human and organizational factors (HOFs) to achieve safe and successful human performance by reducing the risk of errors. In this sense, the concept of maturity models aims to help companies in the integration of these factors by assessing the current level of maturity and define future areas for improvement. The HOFs maturity model shown in this article is based on the five main factors that can impact human performance and safety positively. The measurement methodology consists in applying the Fuzzy Analytic Hierarchy Process (FAHP) method to calculate the weighting of the elements of the model since they do not have the same importance. Next, the Fuzzy Comprehensive Evaluation Method (FCEM) is used to determine the maturity level in terms of HOFs among the five proposed by performing an assessment of the sub-factors using a questionnaire. The purpose of using fuzzy logic is to deal with vagueness and uncertainty of the human reasoning. The proposed model and methodologies are implemented to bring out the current situation of a Moroccan mining organization and identify the elements that require more effort to reach the next level of maturity.

1. Introduction

High risk organizations are increasingly aware of the importance of human and organizational factors and their impact on health and safety on work. The integration of these factors allows companies to achieve safe and successful human performance, by understanding the interactions between humans and other elements of complex systems in order to predict and reduce accidents and incidents.

There are several approaches bringing together the elements that contributed to major accidents in the past, from the implementation of the Seveso I and II Directives to the integration of the Human and Organizational Factors. However, it is difficult for the company to choose the right approach and to know which specific areas of HOFs need to be prioritized. Therefore, the frequently asked questions are : Where are we and where do we want to be ?. These questions are used to define the current state of the company and the desired objective.

The maturity model concept has been developed to answer these questions, by assisting companies in the maturity assessment

process and identifying the required areas for improvement. The HOFs maturity model describes the main characteristics allowing a safe human contribution and optimizing the overall performance of the system, it enables the company to determine the maturity in terms of HOFs among a set of suggested levels.

This paper is an extension of work originally presented in "2020 IEEE 6th International Conference on Optimization and Applications" [1], in which a new HOFs maturity model is described. The model is made up of the five crucial factors related to HOFs and proposed five maturity levels that reflect the degree of consideration and integration of these factors through planned procedures.

The difference between the conference paper [1] and this article is the inclusion of fuzzy logic in the weighting calculation phase, by using the Fuzzy AHP method instead of the Analytic Hierarchy Process (AHP) to take into consideration the imprecision and vagueness of human judgements, when assessing the relative importance of the hierarchy elements in order to perform the comparison matrices. Therefore, the proposed methodology consists in combining the FAHP method to

*Corresponding Author: Yousra Karim, yousrakarim@research.emi.ac.ma

determine the weights and the FCEM to assess the HOFs maturity level.

The proposed maturity model is implemented in a Moroccan organization operating in the mining industry to bring out the current situation by measuring its own HOFs maturity level, then define future targets and establish an action plan including the elements to improve.

The next sections are structured as follows: The section "Literature Review" describes the frequently cited models. In section "HOFs Maturity Model" the elements and levels of the model are presented. While section "Methodology" explains the FAHP and FCEM used. A numeric application is given in "Case Study" section, before the "Conclusion".

2. Literature Review

Research indicates a significant growth in the use of maturity models for safety culture assessment and the integration of human and organizational factors, particularly in high-risk areas such as construction and the oil and gas industry. A maturity model describes the key or essential elements that should characterize an organization at a particular maturity level either in relation to safety culture or to HOFs.

The use of maturity models as an assessment tool can be attributed to two main sources, namely, the "Quality Management Maturity Grid (QMMG)" and Westrum's "Typology of Organisations". The QMMG was suggested in 1979, it identified the five stages that an organization goes through to achieve the maximum quality level in all aspects of quality management these are: uncertainty, awakening, enlightenment, wisdom and certainty [2].

Typology of organisational cultures was proposed in 1993. Table 1 describes the characteristics of the three organisational types suggested. To allow a meticulous classification, while increasing employees' accessibility by including familiar terms, the typology was extended to these five levels : Pathological, Reactive, Calculative, Proactive and Generative [3].

Table 1: Westrum's Typology of Organisations

Typology of organisation	Characteristics
Pathological	Information is hidden, messengers are "shot", responsibilities are shirked, bridging is discouraged, failure is covered up, new ideas are actively crushed.
Bureaucratic	Information may be ignored, messengers are tolerated, responsibility is compartmentalized, bridging is allowed but neglected, organisation is just and merciful, new ideas create problems.
Generative	Information is actively sought, messengers are trained, responsibilities are shared, bridging is rewarded, failure causes inquiry, new ideas are welcomed.

In [4], the author used this concept of maturity to create a model named "safety culture maturity model (SCCM)" to help oil companies in the United Kingdom to assess culture maturity level and the actions needed to improve it. The five stages of the SCCM are shown in Figure 1.

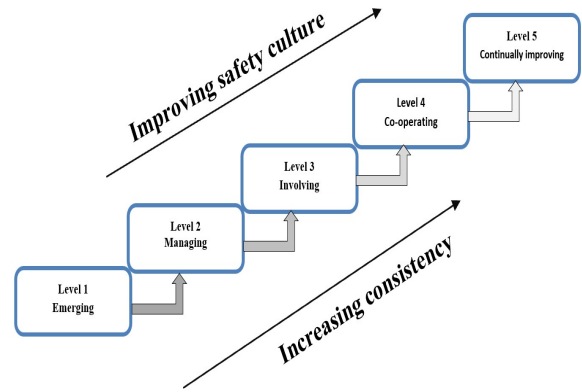

Figure 1: Safety Culture Maturity Model

Based on the SCCM and a thorough literature review of existing models, the author developed in [5] the "Cultural Maturity Model (CMM)" for companies that have an adequate safety management system and wish to evaluate and improve it. Table 2 summarizes the ten elements of the CMM selected to measure key characteristics related to a positive safety culture, and the five developmental stages suggested.

Table 2: Cultural Maturity Model Elements and Stages

Five stages	Ten elements to measure safety culture
1. Documenting	1. Visibility of management commitment
2. Controlling	2. Supervisor visible commitment
3. Engaging	3. Production pressures
4. Participating	4. Organizational learning
5. Institutionalising	5. Job and safety communication
	6. Human and physical resources
	7. Rules and procedures
	8. Trust levels
	9. Training
	10. Workforce involvement

In [6, 7], the author proposed a maturity model, based on the extended Westrum's typology, to describe the evolution of safety culture from the disease stage to a generative end stage. Figure 2 shows the development stages of the model.

From the previous model, a framework was developed to determine the stages of maturity of an organization's safety culture by conducting in-depth interviews with 26 senior oil industry executives working in various multinational and contracting companies [8,9]. It contains 11 tangible or concrete elements related to the safety management system, and 7 less tangible or abstract elements involving perceptions of the workforce. The eighteen elements are divided as follows:

Tangible or concrete elements: 1. Benchmarking, Trends & Statistics; 2. Audits & Reviews; 3. Incident/Accident Reporting, Investigation & Analysis; 4. Hazard and Unsafe Act reports; 5. Work planning including PTW, Journey Management; 6. Contractor Management; 7. Competency/Training; 8. Work-site Job Safety Techniques; 9. Who Checks Safety on a day to day

basis? 10. What is size & status of the HSE Department? 11. What are the rewards of good safety performance?

Less tangible or abstract elements: 1. Who causes accidents in the eyes of management? 2. What happens after an accident? Is the feedback Loop being closed? 3. How do safety meetings feel? 4. Balance between HSE & Profitability? 5. Is management interested in communicating HSE issues with the workforce? 6. Commitment level of the workforce and level of care for colleagues. 7. What is the purpose of procedures?

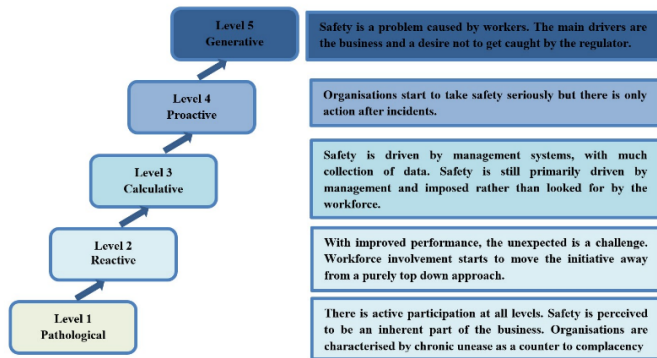

Figure 2: Safety Culture Model of Hudson

Maturity models have also been used to measure the level of integration of human factors, as they are essential to achieve safe human performance. The “Human Factors Maturity Model (HFMM)” was designed to help companies wishing to improve their maturity level by determining which items require additional effort in the future [10]. It includes 5 levels from the first Emerging level to a final level called Leading, and 12 key elements of human factors that highlight their relevance to major accidents in the literature. For each item, a card sorting methodology is used to assess the current level of maturity by representatives of organizations, then define the requirements needed to improve maturity to the next level. The elements and levels of the HFMM are shown in Table 3.

Maturity models have been used by several industries in the literature following different measurement methods, which often require precise human judgment to choose one of the maturity levels. And since human judgment is imprecise and vague, the model proposed in this article includes fuzzy logic to remedy this issue [11].

Table 3: Human Factors Maturity Model

HFMM Levels	HFMM Elements
1. Emerging	1. Managing Human Failure (including maintenance)
2. Transitional	2. Human Factors in Incident Investigation
3. Planned	3. Design and Development of Procedures
4. Proactive	4. Training and Competence
5. Leading	5. Staffing and Workload
	6. Managing Organisational Change
	7. Safety-Critical Communications
	8. Human Factors in Design
	9. Fatigue and Shift work
	10. Safety Culture and Behaviour
	11. Contractor Management
	12. Managing Performance under Pressure

3. HOFs Maturity Model

A review of the literature was carried out to select the human and organizational factors that affect human performance, in order to reduce accidents and improve the safety level of organizations. The maturity model presented in this article is developed based on the five key factors [1] cited by the Rail & Safety Standards Board (RSSB) in their guide “Understanding human factors” [12] namely:

- Design F1: The consideration of HOFs in the design is a crucial step to ensure that the organization does not miss major opportunities for improving human performance at work and to eliminate the risk of accidents, loss of personnel and significant financial costs.
- Training F2: Numerous studies demonstrate the effectiveness of training in business growth. The results of training are concrete and measurable both in productivity and in the professional development of the staff. Although a company may have carefully screened its employees, training within the company itself will allow them to have the same vision of things and move in the same direction.
- Staffing F3: Recruiting and retaining the right people is critical to the success of every organization. Selecting the wrong skills can lead to organizational weakness.
- Culture F4: Culture is essential to allow the organization to differentiate itself. In terms of image on the one hand, it has advantages both internally and externally to consumers. It is indeed a source of cohesion and motivation of employees and it limits conflicts.
- Conditions F5: The improvement of working conditions to ensure the well-being of the employee must first affect health and safety. All employees wish to carry out their work in a healthy and pleasant atmosphere, in which they can feel the recognition and consideration of their efforts.

Table 4 lists the sub-factors linked to each of the five factors, which allow to determine the maturity level in terms of HOFs among the five presented in Figure 3. [1]

Table 4: HOFs Maturity Model

Goal: Human Performance and Safety	Human and Organizational Factors	Sub-Factors
	1. Design F1	Equipment Design F11 Workplace Design F12 Job Design F13
	2. Training F2	Effective Training Programme F21 Training Appraisal F22
	3. Staffing F3	Recruitment F31 Retention F32
	4. Culture F4	Leadership F41 Management F42 Teamworking F43 Communication F44 Change F45
	5. Conditions F5	Morale & Motivation F51 Stress F52 Workload F53 Shift Work F53

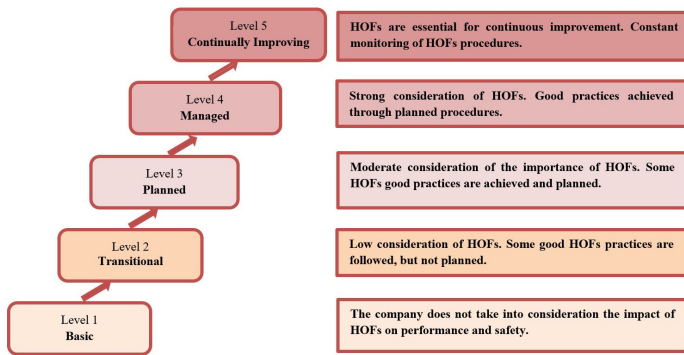

Figure 3: Maturity Levels Description

To ensure the understanding and appropriate application of the model, a set of good practices related to each sub-factor have been listed. For the retention sub-factor, as an example, the best practices relevant to employee satisfaction and retention are presented below:

- Offer rewards.
- Listen to your staff.
- Carry out training.
- Improve your team culture.
- Develop career paths.
- Understand why people quit.
- Maintain dialogue with staff

Table 5 provides an overview of the questionnaire developed to facilitate data collection during the maturity assessment. The questions are established from the proposed model to bring out the information concerning the sub-factors.

4. Measurement Methodology

The methodology proposed in this work is based on the use of FAHP method instead of AHP to calculate the factors and sub-factors weightings, that reflect their impacts on human performance and safety. For the HOFs maturity level assessment, the FCEM method is utilized to consider the imprecision and uncertainty of decision-makers' judgment.

Below are explained the FAHP and FECM methods used for the model implementation.

4.1 Fuzzy AHP

Fuzzy AHP method is an extension of the AHP introduced in 1970 [13], used to solve complex decision-making problems. This method deals with the ambiguity and vagueness of decision-makers that cannot be addressed by precise values by integrating fuzzy logic [11].

Many extensions of AHP have been proposed by several authors such as the geometric mean method [14]. In this paper, the HOFs model utilized the extent analysis approach proposed in [15] given the simplicity and ease of application using triangular fuzzy numbers (TFNs) for the pairwise comparisons.

The steps of the FAHP method are [16, 17]:

Step 1: Construct the AHP hierarchy by identifying factors and sub-factors of the model.

Step 2: Compare by pair the factors and sub-factors to calculate the local weights using the fuzzy scale [18] shown in Table 6 and Figure 4. This scale is used in Chang's FAHP method described below.

Figure 4: Linguistic Scale for Relative Importance

Assume that $X = \{x_1, x_2, \dots, x_n\}$ is an object set, and $U = \{u_1, u_2, \dots, u_m\}$ is a goal set. For each object, an extent analysis is performed for each goal g_i . Therefore, m values of the extent analysis are obtained for each object, as follows:

$$M_{g_i}^1, M_{g_i}^2, \dots, M_{g_i}^m \quad i=1, 2, \dots, n. \quad (1)$$

where $M_{g_i}^j$ ($j=1, 2, \dots, m$) are TFNs. A TFN is simply denoted (l, m, u) .

1) The value of fuzzy synthetic S_i for the i -th object is:

$$S_i = \sum_{j=1}^n M_{g_i}^j \times \left[\sum_{i=1}^n \sum_{j=1}^m M_{g_i}^j \right]^{-1} \quad (2)$$

The fuzzy addition operations are performed with m values.

$$\sum_{j=1}^m M_{g_i}^j = (\sum_{j=1}^m l_j, \sum_{j=1}^m m_j, \sum_{j=1}^m u_j) \quad (3)$$

$$\sum_{i=1}^n \sum_{j=1}^m M_{g_i}^j = (\sum_{i=1}^n l_i, \sum_{i=1}^n m_i, \sum_{i=1}^n u_i) \quad (4)$$

Then, the inverse vector of (4) :

$$\left[\sum_{i=1}^n \sum_{j=1}^m M_{g_i}^j \right]^{-1} = \left[\frac{1}{\sum_{i=1}^n u_i}, \frac{1}{\sum_{i=1}^n m_i}, \frac{1}{\sum_{i=1}^n l_i} \right] \quad (5)$$

2) The degree of possibility of $S_2 = (l_2, m_2, u_2) \geq S_1 = (l_1, m_1, u_1)$ is defined as:

$$V(S_2 \geq S_1) = \sup[\min(\mu_{S_1}(x), \mu_{S_2}(y))] \quad (6)$$

Which can be expressed equivalently as follows:

$$V(S_2 \geq S_1) = \text{hgt}(S_2 \cap S_1) =$$

Table 5: HOFs Questionnaire Overview

Questions	Answers	Questions	Answers
1. Is the design of the equipment meet user needs (visibility, workflow, constraints, environment, workload, etc.)?	1. All equipment takes into consideration the needs of the users. 2. An important part of the equipment meets the needs of users. 3. Only critical equipment considers the needs of users. 4. Some critical equipment takes user needs into account. 5. No equipment follows user needs.	7. How do you find the efforts made by the company to keep the people recruited?	1. Excellent. 2. Good. 3. Medium. 4. Basic. 5. No efforts.
2. How do you assess the design of the workplace?	1. Excellent design (The company is always looking for ways to improve). 2. Good design. 3. Medium design. 4. Basic. 5. Poor (The company is not aware of the impact of good design).	8. How do you rate the involvement of managers and leaders in the HOFs procedures?	1. Extreme involvement. 2. Good involvement. 3. Medium involvement 4. Basic involvement. 5. No involvement.
3. How do you perceive the job design (job descriptions) produced by the company?		9. How do you perceive the involvement and commitment of employees in change projects?	
4. How do you rate the effectiveness of the training programs?	1. Extremely effective. 2. Effective 3. Medium effectiveness. 4. Low effectiveness. 5. Not at all effective.	10. How do you perceive the supervision of teamwork within your company?	1. Extremely supervised. 2. Good supervision. 3. Medium supervision. 4. Basic supervision 5. No supervision.
5. How do you perceive the selection and recruitment process?		11. How do you rate the quality of communication?	1. Excellent. 2. Good. 3. Medium. 4. Basic. 5. Insufficient.
6. How do you perceive the process of assessing the trainings carried out by the company (reaction of trainees, learning objectives...)?	1. Excellent assessment 2. Good assessment. 3. Medium assessment. 4. Baseline assessment. 5. Insufficient assessment.	12. How would you rate the practices put in place by the company to improve morale and motivate employees at work?	1. Excellent. 2. Good. 3. Medium. 4. Basic. 5. Insufficient.
		13. How do you see the strategy adopted by the company to manage stress?	
		14. How do you perceive the workload?	1. In standards 2. Normal but disrupted on some occasions. 3. Moderately excessive. 4. Excessive . 5. Extremely excessive.
		15. How do you perceive the work shift planning ?	

Table 6: Linguistic Scale for Relative Importance

Linguistic scale for relative importance	Triangular Fuzzy Scale
Just Equal	(1, 1, 1)
Equally Important (EI)	(1/2, 1, 3/2)
Weakly more important (WMI)	(1, 3/2, 2)
Strongly more important (SMI)	(3/2, 2, 5/2)
Very strongly more important (VSMI)	(2, 5/2, 3)
Absolutely more important (AMI)	(5/2, 3, 7/2)

$$\mu_{S_2}(d) = \begin{cases} 1, & \text{if } m_2 \geq m_1 \\ 0, & \text{if } l_1 \geq u_2 \\ \frac{l_1 - u_2}{(m_2 - u_2) - (m_1 - l_1)}, & \text{otherwise} \end{cases} \quad (7)$$

where d is the ordinate of the highest intersection point D between μ_{S_1} and μ_{S_2} (Figure 5).

Both the values of $V(S_2 \geq S_1)$ and $V(S_1 \geq S_2)$ are needed to compare S_1 and S_2 .

Figure 5: Intersection Between S_1 and S_2

- 3) The degree possibility for a convex fuzzy number to be greater than k convex fuzzy numbers S_i ($i=1, \dots, k$) can be expressed by:

$$V(S \geq S_1, S_2, \dots, S_k) = V[(S \geq S_1), \dots, (S \geq S_k)] = \min V(S \geq S_i), i=1, \dots, k. \quad (8)$$

$$\text{Assume that } d'(A_i) = \min V(S_i \geq S_k), \quad (9)$$

for $k=1, \dots, n, k \neq i$. Then the weight vector W' is given by:

$$W' = (d'(A_1), d'(A_2), \dots, d'(A_n))^T, \quad (10)$$

where A_i ($i = 1, 2, \dots, n$) are n elements.

- 4) Finally, the normalized weight vectors are obtained:

$$W = (d(A_1), d(A_2), \dots, d(A_n))^T, \quad (11)$$

where W is a crisp number.

4.2 Fuzzy Comprehensive Evaluation Method

The fuzzy comprehensive evaluation method is based on fuzzy logic theory developed in [11]. Unlike the system of classical logic, it aims to deal with uncertainty, subjectivity, and vagueness of human reasoning. The FCEM principles are used with the proposed model to assess the maturity level of HOFs as follows [1, 19, 20, 21, 22]:

Let $V = \{V_1, V_2, \dots, V_p\}$, the evaluation set.

Step 1: Construct the evaluation matrix R_{ij} named the second-class index membership matrix.

$$R_{ij} = \begin{pmatrix} R_{i1} \\ \vdots \\ R_{ij} \\ \vdots \\ R_{im} \end{pmatrix} = \begin{bmatrix} r_{i11} & \cdots & r_{i1p} \\ \vdots & & \vdots \\ r_{im1} & \cdots & r_{imp} \end{bmatrix} \quad (12)$$

where

R_{ij} is a fuzzy relationship from F_i 's sub-factors (F_{ij}) to V .

Where: $i=1, \dots, n$ is the number of factors to be evaluated.

$j=1, \dots, m$ is the second index of i , and m is the number of sub-factors (F_{ij}) of a factor (F_i).

R_{ij} is a fuzzy relationship from F_{ij} to V .

$$(r_{ij1} \quad \cdots \quad r_{ijk} \quad \cdots \quad r_{ijp}) = (l_{ij1}/\beta \quad \cdots \quad l_{ijk}/\beta \quad \cdots \quad l_{ijp}/\beta) \quad (13)$$

$\beta = \sum_{k=1}^{k=p} l_{ijk}$ is the experts' number, $k=1, \dots, p$ is the evaluation level.

Step 2: Compute the matrix R named the first-class index membership matrix.

$$R = \begin{pmatrix} R_1 \\ R_2 \\ \vdots \\ R_n \end{pmatrix} = \begin{bmatrix} r_{11} & \cdots & r_{1p} \\ \vdots & & \vdots \\ r_{n1} & \cdots & r_{np} \end{bmatrix} \quad (14)$$

$$\text{where } R_i = W_{ij} \circ R_{ij} = (r_{i1} \quad \cdots \quad r_{ip}) \quad (15)$$

W_{ij} is the weight vector obtained from the FAHP method.

Step 3: Calculate the maturity vector M :

$$M = W R = (r_1 \quad \cdots \quad r_p) \quad (16)$$

$$W = (W_1 \quad \cdots \quad W_i \quad \cdots \quad W_n) \text{ with } W_i \text{ is the weight } F_i.$$

Finally, the maturity level is determined according to the principle of maximum membership degree law as following:

If $r_k = \text{Max}(r_1 \quad \cdots \quad r_p)$, the maturity level is k .

5. Case study

The HOFs maturity model and the methodologies developed in this paper are implemented in a Moroccan organization operating in the mining industry to define potential future steps essential to improve human performance and safety level. Therefore, a group of decision makers was selected for the acquisition of input data and the application of the FAHP and FCEM methods. The comparisons matrices were done by the representatives of managers, supervisors and operators. Unlike the assessment step, which was carried out separately, first with the Group 1 of managers, next with the Group 2 of supervisors and site operators.

5.1. Results

The representatives performed the pairwise comparisons of factors and sub-factors listed in Table 4 using the fuzzy scale illustrated in figure 6 [18], and obtained the results shown in Tables 7, 8, 9, 10, 11, 12.

Table 7: Weights and Comparison Matrix of Factors

Goal	F1	F2	F3	F4	F5	Weights
F1	(1, 1, 1)	(3/2, 2, 5/2)	(1/2, 1, 3/2)	(1/2, 2/3, 1)	(2/5, 1/2, 2/3)	0.17
F2	(2/5, 1/2, 2/3)	(1, 1, 1)	(2/3, 1, 2)	(2/5, 1/2, 2/3)	(2/5, 1/2, 2/3)	0.07
F3	(2/3, 1, 2)	(1/2, 1, 3/2)	(1, 1, 1)	(2/5, 1/2, 2/3)	(1/3, 2/5, 1/2)	0.10
F4	(1, 3/2, 2)	(3/2, 2, 5/2)	(3/2, 2, 5/2)	(1, 1, 1)	(1/2, 2/3, 1)	0.29
F5	(3/2, 2, 5/2)	(3/2, 2, 5/2)	(2, 5/2, 3)	(1, 3/2, 2)	(1, 1, 1)	0.37

Factors and sub-factors weights are computed using Chang's FAHP method [15] described above. A numerical overview of the steps is given below to calculate weights shown on the right of Table 7.

- 1) $S_{F1} = (0.10, 0.18, 0.30)$; $S_{F2} = (0.08, 0.12, 0.23)$;
 $S_{F3} = (0.08, 0.14, 0.26)$; $S_{F4} = (0.15, 0.25, 0.41)$;
 $S_{F5} = (0.19, 0.31, 0.50)$.
- 2) $V(S_{F1} \geq S_{F2}) = 1$; $V(S_{F1} \geq S_{F3}) = 1$; $V(S_{F1} \geq S_{F4}) = 0.69$;
 $V(S_{F1} \geq S_{F5}) = 0.46$;
 $V(S_{F2} \geq S_{F1}) = 0.68$; $V(S_{F2} \geq S_{F3}) = 0.91$;
 $V(S_{F2} \geq S_{F4}) = 0.38$; $V(S_{F2} \geq S_{F5}) = 0.17$;
 $V(S_{F3} \geq S_{F1}) = 0.77$; $V(S_{F3} \geq S_{F2}) = 1$; $V(S_{F3} \geq S_{F4}) = 0.49$;
 $V(S_{F3} \geq S_{F5}) = 0.28$;
 $V(S_{F4} \geq S_{F1}) = 1$; $V(S_{F4} \geq S_{F2}) = 1$; $V(S_{F4} \geq S_{F3}) = 1$;
 $V(S_{F4} \geq S_{F5}) = 0.77$;
 $V(S_{F5} \geq S_{F1}) = 1$; $V(S_{F5} \geq S_{F2}) = 1$; $V(S_{F5} \geq S_{F3}) = 1$;
 $V(S_{F5} \geq S_{F4}) = 1$.
- 3) $d'(A_{F1}) = V(S_{F1} \geq S_{F2}, S_{F3}, S_{F4}, S_{F5}) = 0.46$;
 $d'(A_{F2}) = V(S_{F2} \geq S_{F1}, S_{F3}, S_{F4}, S_{F5}) = 0.17$;
 $d'(A_{F3}) = V(S_{F3} \geq S_{F1}, S_{F2}, S_{F4}, S_{F5}) = 0.28$;
 $d'(A_{F4}) = V(S_{F4} \geq S_{F1}, S_{F2}, S_{F3}, S_{F5}) = 0.77$;
 $d'(A_{F5}) = V(S_{F5} \geq S_{F1}, S_{F2}, S_{F3}, S_{F4}) = 1$.
- 4) Then, the weight vector of factors is obtained:
 $W = (d'(A_{F1}), \dots, d'(A_{F5}))^T = (0.17, 0.06, 0.10, 0.29, 0.37)$.

	F54	0.34	0.00	0.00	0.58	0.17	0.25

The sub-factors' weights and the assessment results are subsequently used to determine the first-index membership matrix of the two groups represented in Tables 15, 16.

Table 15: First-Class Index Membership Matrix of Group 1

Factors	Weights	Levels				
		B	T	P	M	CI
F1	0.17	0.00	0.00	0.42	0.44	0.14
F2	0.07	0.03	0.13	0.36	0.42	0.06
F3	0.10	0.00	0.20	0.21	0.38	0.21
F4	0.29	0.00	0.01	0.27	0.44	0.28
F5	0.37	0.04	0.19	0.48	0.29	0.00

Table 16: First-Class Index Membership Matrix of Group 2

Factors	Weights	Levels				
		B	T	P	M	CI
F1	0.17	0.00	0.13	0.49	0.30	0.08
F2	0.07	0.05	0.24	0.25	0.34	0.12
F3	0.10	0.04	0.21	0.25	0.42	0.08

F5	0.37	0.07	0.24	0.45	0.16	0.08

Finally, the HOFs maturity vector (HOFM) is determined using Tables 15, 16 and factors' weights.

$$\text{HOMF1}(\text{Group 1}) = (0.02, 0.10, 0.37, 0.38, 0.13)$$

$$\text{HOMF2}(\text{Group 2}) = (0.03, 0.16, 0.37, 0.33, 0.11)$$

5.2. Discussions

According to the maximum membership degree law and maturity vectors (HOMF1, HOMF2) obtained from both groups, the maturity level of the company is "Managed" for Group 1 and "Planned" for Group 2. Therefore, the managers assume that there

is a strong consideration of HOFs, and good practices are achieved through planned procedures. While supervisors and operators suppose that the impact of HOFs on safety and human performance is moderately taken into account, and some good practices related to HOFs are fulfilled in a planned manner.

The maturity levels of factors are deducted from the first-class index membership matrices (Tables 15, 16). Then, the results are presented on spider diagrams below. Figure 6 shows the factors' maturity levels obtained from the assessment carried out with Group 1 of managers, and Figure 7 shows the levels obtained from the evaluation undertaken by Group 2 consisting of supervisors and operators.

Figure 6: Spider Diagram of Group 1

The two diagrams show that no factor is judged at level 5 "Continually Improving". The results obtained are close for both groups despite the hierarchical diversity. The three factors:

“Staffing”, “Training” and “Culture” are at the same maturity level 4 “Managed”. The factor “Conditions” is also at level 3 “Planned” for the two groups. However, the “Design” factor is at level 4 “Managed” for Group 1 and level 3 “Planned” for group 2.

Figure 7: Spider Diagram of Group 2

The purpose of this model is not only to assess maturity in terms of HOF, but also to assist the company in defining future improvement steps to reach the next level of maturity. For this mining organization, it is necessary to provide more effort regarding the "Conditions" factor since it has the highest weighting, and it is evaluated at level 3 for both groups. Then, for the factor "Design" which has such an important impact, it is recommended to take into consideration the opinions of supervisors and operators to improve the current state and satisfy their needs.

After this study, an action plan made up of some good practices essential for improvement was established based on elements

weights and the assessment carried out by the groups. Table 17 shows a summary of the proposed action plan.

6. Conclusion

There is a remarkable growth in the use of maturity models to assess safety culture and HOFs, but also different variations in the elements of these models and measurement methodology. These models can be used for maturity assessment in any industry and as an improvement tool by identifying strengths and weaknesses related to a set of key elements.

This work introduces a maturity model related to HOFs made up of the five factors essential to human performance and safety. The model defines five stages of maturity, from the lower level where the company does not take into consideration the impact of HOFs, to the upper level characterized by continuous enhancement and permanent follow-up of HOFs procedures. The measurement methodology differs here in the first phase, which consists of using Fuzzy AHP method instead of AHP to calculate the weights. And for the second phase, a questionnaire is included to facilitate the collection of data used in the FCEM method.

The HOFs model is applied in a Moroccan mining company to determine the current maturity level and improve it through an appropriate action plan. Teams of managers, supervisors and operators who participated in implementing the model have used it successfully, and it has proven to be a useful tool for evaluation and improvement.

Future work will focus on improving the current HOFs maturity model by testing and adapting it for a wide range of companies, so that it is not limited to a particular area. Also, conducting a sensitivity analysis [23] to test the robustness of the model and better understand relationships between the elements.

Table 17: Improvement Action Plan Related to HOFs

Element	Good practices
Morale and Motivation	<ul style="list-style-type: none"> • Show them the results of their efforts. • Give them responsibilities. • Ask them what motivates them. • Give them some advantages. • Offer them training courses.
Stress	<ul style="list-style-type: none"> • Stress management training: Ask employees to take relaxation and time management courses and take internships or do assertiveness exercises. • Ergonomics and design of the professional environment: Improve the equipment used at work and the physical working conditions. • Improve management: Improve the attitude of managers towards work stress, their knowledge and understanding of this problem and their ability to tackle it as effectively as possible. • Company development: Implement better work and management systems. Develop a friendlier corporate culture and a spirit of mutual aid.
Workload	<ul style="list-style-type: none"> • Identify your team's workload and capacity. • Allocate resources and manage individual workloads. • Check in with your team and adjust workloads if necessary. • Improve efficiency under over workloads. • Adopt a work management tool

ABSTRACT

This paper describes an experimental setup that employs ultrasound to scan an area. This method utilizes ultrasonic waves to scan the surface of a submerged object in a water-coupled medium. A pulse-echo mode is used, and quantitative data are collected at various positions using a two-dimensional automated table. A microcontroller controls the motion of the scanner, whereas a script developed in MATLAB controls the ultrasonic pulser receiver process. The MATLAB script ultimately controls and correlates between the scanner movement and ultrasonic pulser receiver process. The intensities of the reflected waves are captured and used to generate the A-scan image for the external surface. The surface profile of the scanned object can be clearly obtained using the time arrival of the reflected waves. The experimental results based on a one-pound coin indicate that the precision of the proposed process. This simple and efficient method can be used in different engineering applications with minimum errors.

1. Introduction

Ultrasonic waves are commonly utilized in numerous applications such as nondestructive testing (NDT), object recognition, and medical imaging. They have been used as an inspection tool in different materials [1]. Ultrasonic waves can spot any irregularities contained inside the tested specimens that cannot be identified visually. They can be used in different medical devices such as the application of ultrasound imaging for pregnancy [2]. Ultrasonic inspections are listed as a non-destructive testing method because the procedure implemented does not cause any damage to the tested objects [3]. Pulse-echo mode is the most widely used method for inspection. The key benefit of this approach is that only one side of the tested object should be accessible. This broadens its applicability to accommodate for different applications such as crack detection and surface imaging [4].

Several applications include scanning a specimen's surface in order to obtain an image that represents the object. However, this process should include a 2D or 3D automated scanner coupled with the ultrasonic devices [5]. Therefore, a reliable control system should be designed and implemented to ensure correct images are obtained. The surface imaging can be used in different industrial applications [6]. It can also find several applications in the oil and gas industry. The integrity of the oil well cement placement can

play a vital role in the success of the drilling operations. Ultrasonic imaging methods can be used for inspecting the cement integrity. This ensures a good sealing layer is obtained between the well and the formation [7]. The cement integrity becomes a critical issue when extended wells are to be drilled [8].

Many applications require using coupling a scanner with another measuring device e.g. ultrasonic pulser-receiver to record real-time data. Commercial tools that do this job are available and can be easily purchased. These tools were used by different researchers in their projects [9]. However, the cost of these tools might be very expensive. Furthermore, the recorded data from the commercial devices might be limited to certain parameters such as amplitude-based data. This limit can be bypassed when the experiment is manually designed, and the script codes are prepared by the user. Some researchers used an ultrasonic device that utilizes LabVIEW for data acquisition [10]. However, in that application, the ultrasonic device was fixed and hence no movement was allowed.

To the best of the author's knowledge, there are not enough published articles that focus mainly on the ultrasonic scanner setup. Most of the articles focus on the application of this method instead. This makes it difficult to replicate these experiments without purchasing expensive equipment and services. In this study, the main focus is on the experimental setup that can produce a two-dimensional image of any surface. This setup utilizes

*Corresponding Author: Kamel F. Bou-Hamdan, kamelbh@live.com

equipment that are of lower cost than the commercial setups used in previous studies. The scanner movement and data acquisition process are ultimately controlled through a custom-written script in MATLAB. A pre-programmed microcontroller is used as an interfacial connection between the scanner and MATLAB. An ultrasonic pulser-receiver device is used as the interface between the transducer and MATLAB. This design might attract researchers who are looking for simple and cost-effective surface imaging methods using ultrasonic waves. All the equipment and control systems are addressed in the text. This article is an extension version for a previously published conference paper [5].

2. Pulse-echo Technique Background

Figure 1a displays the principles of this method. A transmitter is used to send out a pulse wave into the body. When a boundary is reached, e.g. the back wall or a deficit in the material, the wave is reflected back towards the receiver where it is captured and recorded [3]. In general, the pulse-echo mode uses the same ultrasonic transducer for transmitting and receiving the waves, as shown in Figure 1b.

Different types of sound waves propagate in materials, such as longitudinal and shear waves. The latter cannot travel in liquids or gases, unlike the longitudinal waves which can exist in any medium [11]. The speed of sound is not constant but depends on the material it passes through. This speed is roughly 340 meters per second in air, 1500 in water and over 2000 in solids. Acoustic impedance (Z), which describes the resistance of a material to sound waves, depends on the density and speed of sound [3]

$$Z = \rho \cdot c, \quad (1)$$

where c is the speed of sound in the propagating material, whereas ρ is the density of the material.

Ultrasonic waves follow the same principles of acoustic waves. When a wave hits an interface, part of it will undergo reflection while the other part will undergo refraction [3]. The acoustic impedance can be used to determine the reflection and transmission behaviour taking place at the boundaries of two objects in contact. The intensities of the divided waves depend on the material properties at the boundary. Ultrasonic waves of high frequency cannot propagate in air due to their low acoustic impedance; therefore, a wave passing through a solid material will

mostly undergo reflection when encountering an air interface. The reflection coefficient (R) can be obtained using [3]

$$R = (Z_2 - Z_1) / (Z_2 + Z_1), \quad (2)$$

where Z_1 and Z_2 represent are the acoustic impedance of the materials in contact. Three possibilities might be encountered when solving (2), as follows:

- $Z_2 \gg Z_1$, e.g. solid-air interface, then R equals to 1 which suggests that all the waves are reflected back towards the receiver;
- $Z_1 = Z_2$, e.g. two similar materials in contact, then R equals 0, suggesting that all the waves were transmitted to the other end. This means that no signal is read at the receiver.
- $Z_2 < Z_1$, then R would be a negative value; this change in sign suggests a phase shift in the signal [3].

Furthermore, as sound travels through a medium, the intensity of the wave reduces due to attenuation. Attenuation is a result of two mechanisms: scattering and absorption. Wave scattering describes the spreading of sound waves in different directions besides its original path, whereas absorption refers to the losses due to energy conversion within the material, e.g. mechanical energy converts to heat. The frequency profoundly influences the degree of attenuation and the medium it propagates in [3].

3. Methodology

3.1. Materials

The main equipment that are used in this experiment are: an ultrasonic transducer, an ultrasonic pulser-receiver, a microcontroller, a scanner, and a PC with MATLAB software. All of these equipment are briefly discussed in the following text.

Ultrasonic transducer – This device is used to transmit and/or receive acoustic energy. A focused ultrasonic transducer of 10 MHz rating was selected for this experiment. The major benefits of using a high frequency transducer is to improve the accuracy and quality of the output image. Generally, unfocused transducers are not used for scanning purposes as they cannot attain high resolutions without the use of extra lenses [12]. Passive focusing techniques could be utilized to improve the accuracy of these transducers [13].

Figure 1: Pulse-echo mode. (a) Using two separate transmitter and receiver transducers; (b) Using a single transmitter/receiver transducer (Transceiver)

Ultrasonic waves of high frequencies cannot pass in air. Hence, a connecting fluid is regularly used to provide a medium that allows for wave propagation [14]. Therefore, the ultrasonic transducer was submerged in standing water for the full extent of the experiment.

In order to focus the waves accurately, the exact distance between the transducer and the object to be scanned should be predefined. This will lead to higher resolution for the scanned image. This distance represents the location of the maximum wave intensity and is identified by reading the focal length rating of the transducer. This value will change with different types of transducers.

The focal spot diameter is a critical parameter to be considered during the design stage since it can impact the resolution. If this attribute has a value lower than that of the scanned object, better resolutions would be achieved. The focal spot diameter (d) can be calculated using the following relation [3]:

$$d = (1.028 c_w l_w) / (1000 f D), \quad (3)$$

where d is in mm, l_w and c_w are the speed of sound in m/s and focal length in mm in standing water, f is the nominal frequency in MHz and D is the diameter of the transducer in mm. This relation that exists between the focal spot diameter and frequency is represented in Figure 2 for simplicity. The two parameters are inversely proportional, where a smaller focal spot (better resolution) can be attained using high frequency.

The ultrasonic transducer that was used is displayed in Figure 2 as a red mark. It is of 10 MHz frequency, 25.4 mm element diameter, and 51 mm focal length in water. When using these values in (3), the focal spot diameter can be calculated to be around 0.3 mm in water.

Figure 2: Variations of the focal spot diameter with frequency

Ultrasonic pulser receiver (UPR) - This instrument is employed to provide the excitation voltage for the transducer. It can either be manually designed for a given application or purchased from a manufacturing company. The device which was used in this experiment was produced by Lecoer Electronique. It contains two channels, a transmitter and a receiver. The first channel can be used to direct the electrical pulses to the transducer which then sends out ultrasonic waves. The second channel receives the electrical signals from the ultrasonic transducer when it detects

ultrasonic waves. The ultrasonic pulser receiver can be used in two different modes: either in single mode, as a transmitter or receiver, or in full mode, both as a transmitter and as a receiver.

Automated table (Scanner) – This device is used to guide the transducer in different directions. In this experiment, the scanner can move in two horizontal directions. This is the minimum requirements for scanning an area. The movement is employed by the use of a dynamic gantry, that is connected onto a lead screw of 250 mm length. The lead screw has a 2mm pitch of 2 mm and four threads (Four Start). Therefore, the regular actual lead of is 8 mm per revolution.

Stepper motors are used to provide rotation for the lead screw and hence, movement of the gantry. The stepper motors utilized have a high torque value of 114 oz. These motors must undergo 200 steps to complete a full revolution. Hence, a 40 μ m linear displacement per step can be easily achieved. Two stepper motor drivers (DRV8825) were used to control the motors. Each driver can deliver a maximum of 45 V output voltage and 2.5 A current. The drivers employ two current sinewaves along with a phase shift of 90°. This allows a smoother motor operation. Additionally, the drivers can be used in micro-stepping modes. In this experiment, steps of 100 μ m were used.

Figure 3 shows the assembled materials. The automated table was fixed to a larger supporting frame. A clamp, made up of polycarbonate material, was fixed to the lower end of the automated table. This clamp was used to hold the ultrasonic transducer. Limit switches were installed at the ends of the lead screw to prohibit any movement beyond a given limit to avoid stalling of the motor.

Figure 3: Assembly of the experimental setup

A micro-controller electronic board, that is coded using C++ language, was used to provide suitable control over the stepper motors. In addition to that, it allows for micro-stepping to be attained. This board consists of 6 analogue inputs and 14 digital input/output pins. The connection circuit for the scanner is displayed in Figure 4. The micro-controller is connected to a power supply through an adaptor (Not shown in figure) and to the PC through a USB cable. The microcontroller is connected to the stepper motor drivers using the pins. This allows direct control of the drivers which in turn excite the motors when triggered. A transistor is used in this connection to amplify the electronic signal delivered by the power supply to the motor drivers.

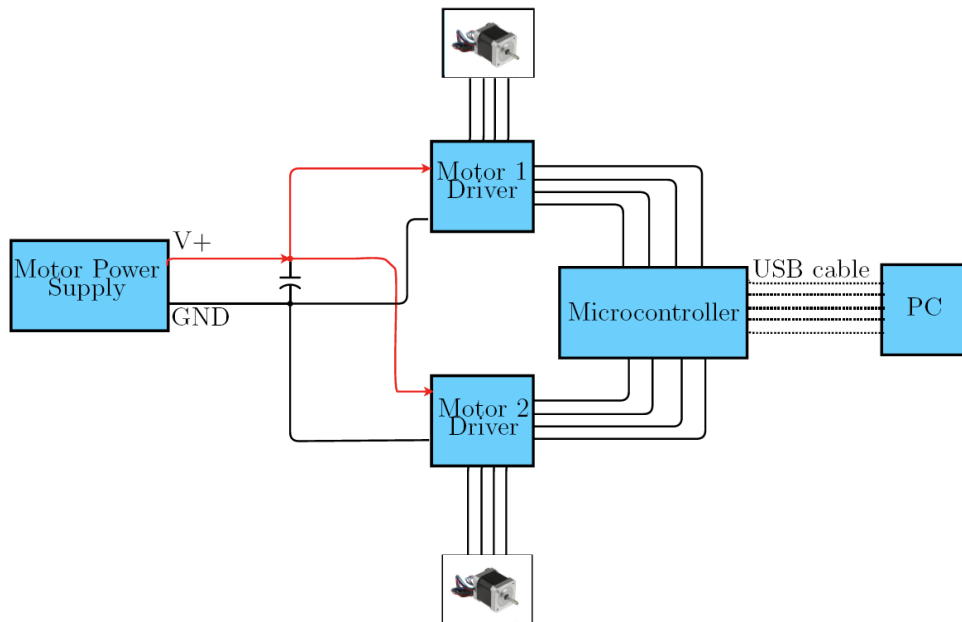

Figure 4: A connection circuit for the scanner.

3.2. Control System

The control system can be divided into 3 main categories: The ultrasonic pulser receiver circuit, the automated table circuit, and the overall system circuit. The control mechanism for these categories are briefly discussed in the following text.

Ultrasonic pulser receiver circuit – The UPR device operates with a script developed in MATLAB. The script enables a series of attributes to be modified including the pulsed frequency, exciting voltage, gain, and others.

The excitation voltage of the ultrasonic pulser receiver is limited to a range of 100 V up to 230 V. The transducer rating can be excited by applying pulsed voltages in from 100 V up to 300 V. This oscillates the inner piezoelectric crystal and produces ultrasonic waves. If the excitation voltage is increased, the reflected signal will record a higher amplitude which can be beneficial when significant wave attenuations are expected.

The gain, which is a signal amplification, is another important parameter that can be regulated to counter the effect of signal attenuation. The recorded signals are not always measurable without tuning the gain value. The ultrasonic pulser receiver is limited to a 80 dB amplification. Nevertheless, laboratory experiments have shown that the measurements become skewed when this is set to 60dB or higher. This is due to increased impact of noise. Therefore, a gain of 40 dB was used in this application.

frequency was fixed at 10 MHz to match the ultrasonic transducer rating. The pulsed width can also be controlled. This width is small, but it can be calculated by analyzing both the amplitude and length of the reflected wave. The assigned pulsed width was nearly 4 μ s.

The pulsed repetition frequency is also regulated by MATLAB. To identify the minimum pulsed repetition time needed for the oscillation of the transducer, it is necessary to obtain the time for each reading to be obtained. This attribute considers the time for the wave to propagate within various materials or layers. In the present scenario, the waves travel through standing water.

The interval distance in water between the coin and transducer should be regulated to maintain the coin in the range of transducer's focal length.

The total travel time of the wave (*TWT*) should be estimated to determine the pulsed repetition frequency. This parameter takes into account the wave transmission and reflection time in water. To find *TWT*, the interval distance between both the transducer and coin should be defined. The following relationship can be used:

$$TWT = (2 WD) / c_w, \quad (4)$$

where *WD* is the interval distance / depth of water (51 mm), and c_w is the speed of sound in standing water (1500 m/s). Adding the value of *TWT* from (4), which equals 68 μ s, to the pulse width gives the minimum total pulse time needed. The pulse width is much smaller than the *TWT* value. Assuming 200 μ s was the pulse repetition time chosen to ensure no more reflected and scattered waves will affect the reading, a 5 kHz pulse repetition frequency would be required. This is achievable using the UPR device. However, the scanning speed is mainly affected by the speed of the automated table, which requires 0.1 seconds interval time to process and act to the movement commands (see text below). This suggests that even a very low pulse repetition frequency can work. In this experiment, a pulse repetition frequency of 1 kHz was chosen as it allows for multiple measurements at each location (lower values could have been used).

Automated table circuit - This circuit is controlled by a microcontroller as shown in Figure 4. A serial interface was developed between MATLAB and the microcontroller using a computer that provides full control over the movement of the device via MATLAB. The script allows for two modes of directional movement:

- To an absolute position,
- Specified number of steps in each direction.

The purpose of this experiment is to scan the area and record the data at each location. As a result, it was found that controlling

the movement by predefined steps would be more appropriate. The total scanning time should be minimized and therefore, the automatic table was designed to scan in a zigzag mode.

Figure 5: Waveform

In general, data points should be closer to one another in order to improve the resolution of the image. This requires setting short

intervals between each scanned location. However, this will lead to an increase in the overall scanning time.

Overall system circuit – MATLAB is employed to provide the main control over the whole system. This approach was achieved by integrating control circuit of the Ultrasonic Pulser-Receiver and scanner. The script has been adapted to obtain three pulses at each position. This is useful in reducing the possible errors during measurement. Figure 5 shows an example of a recorded pulse wave. Figure 6 shows a schematic of the main control process.

The time duration between scanned locations is an important parameter to be determined. This time should be as short as possible without causing biased readings. After several experimental trials, it was found that a time duration of 0.1 seconds was sufficient to maintain accurate data collection.

An A-scan image is a graphical representation of the reflected wave intensity versus time as shown in Figure 5. The script for the UPR can generate this image at every scanned position. This script was designed to collect both the negative and positive peaks of each signal. The amplitude difference, shown in red double-headed arrow, is recorded at every location of the scanned object. This data is then inserted into a matrix form where every element in the matrix represents a location. Once the scan is complete, the matrix will hold around 10,000 different elements. The matrix is then utilized to execute an image which represents the scanned object.

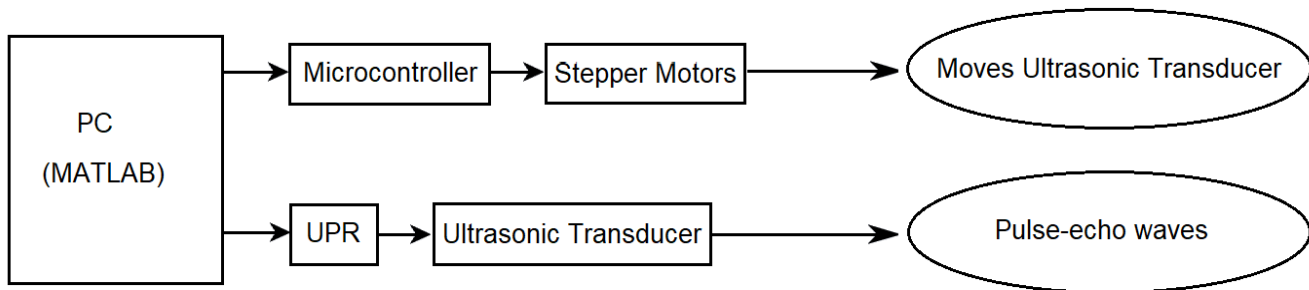

Figure 6: Overall Control System

Figure 7: Scanned image reads accurate coin dimensions

4. Results and Discussion

To check the applicability and efficiency of this method, the experimental design was performed on a one-pound coin. The coin was put inside a water tank. The depth of water above the coin was equivalent to the transducer's focal length of 51 mm. By tracking the amplitude of the ultrasonic pulse, the transducer was then centered on the face of the coin. This process should be done accurately to achieve the best focal spot diameter. A region of 250 mm x 200 mm has been scanned and the image produced is displayed in Figure 7.

Figure 8 Dimensions of the coin as measured by a caliper.

The results reveal that the original coin is clearly mirrored, which confirms the durability of the ultrasonic transducer chosen. The geometry of the coin was examined and linked to the ideal size of the coin as seen in Figure 6. The scanned figure reveals an exterior surface diameter ranging from 23.3 mm to 23.4 mm. This is very similar to the ideal one-pound coin size of 23.43 mm.

To examine the slight size difference, a caliper was used to measure the same coin that was scanned, and the observations are

seen in Figure 7. The measurement taken using the caliper have shown that the real coin size is about 23.3 mm in diameter, which is consistent with the readings obtained from our scanning system. This confirms the precision of the 2D motion of the scanner.

Two methods were used to observe the surface profile of the coin. The first approach was based on the intensity of the reflected wave. This follows the theory that was discussed in (2). Figure 9 shows the intensity of the reflected signals from a planar view. Higher intensities were recorded in the middle part of the coin as that area behaves as a better reflector. This is due to the less irregularities in that area, making it similar to a flat reflective surface.

Figure 10 shows the surface profile of the coin which is based on the intensity of the reflected signal. The boundaries of the coin can be easily distinguished through this view. However, the 3D view of the surface profile might require more scaling to be done to replicate the actual surface of the coin.

Figure 11 shows the surface profile of the coin based on the time of signal arrival. It is clear using this figure that the boundaries and 3D profile of the coin can be well observed and appear to be more realistically distributed. This is because the time approach can be easily linked to actual distances when the speed of sound in the given medium is known, as represented in (4).

These results suggest that both the intensity of the reflected signals and the time of their arrivals can be used to obtain useful data from the surface profile. However, it should be noted that the time approach is more commonly used along with an unfocused transducer, which emits all its waves in a parallel direction. The focused transducer emits waves with different inclination angles for focusing, as done in this experiment. Therefore, it is possible to have minor errors in surface readings when this method is used.

Figure 9 Scanned coin based on intensity of the reflected wave

Figure 10: The surface profile of the scanned coin based on intensity of the reflected wave

Figure 11: The surface profile of the scanned coin based on time of arrival of the reflected wave

Finally, it is important to consider the wave attenuations during the experiments as it can have a great impact on the obtained results. Attenuation coefficient does not depend only on the medium it passes through, but also on the wave frequency. Higher frequencies can result in larger attenuation coefficients. In standing water, the following relation applies to the attenuation coefficient [3]

$$a = 0.217 f^2 \quad (5)$$

where a is the attenuation coefficient in dB/m . The relation between both parameters a and f can be shown in Figure 12. The

red mark displays the ultrasonic transducer that was used in this experiment and shows an attenuation coefficient of 21.7 dB/m .

By combining both (3) and (5), a relation between focal spot diameter and attenuation coefficient in standing water can be obtained as shown in Figure 13. The signal becomes highly attenuated as the focal spot diameter is decreased. This illustrates one of the main issues of ultrasonic scanning where a reasonable decision should be made when selecting the optimum transducer for the experiment. The optimum case should have a small focal spot diameter to ensure a more accurate reading is obtained. On

the other hand, the attenuation coefficient should not be high enough as it might lead to loss of important parts in the signal.

Figure 12: Change in attenuation coefficient with Frequency

Figure 13: Change in focal spot diameter with the attenuation coefficient

5. Conclusion

This paper provides a low-cost approach to the design of a two-dimensional ultrasonic wave scanner. The reliability of this method depends primarily on the transducer's focal spot diameter and the number of data points collected. Using a high-frequency transducer will improve the focal spot diameter. However, the degree of attenuation should be considered since an inverse relation exists between frequency and attenuation coefficient. This becomes critical when the waves are travelling through materials of higher attenuation coefficient than water.

The total number of collected data points for any scanning operation can be enlarged by reducing the interval distance between two successive datasets. But the total scanning time will significantly increase as the number of scanned data points increase.

A 2D image of a scanned object can be clearly obtained using the intensity of the reflected signals, whereas a 3D image (surface profile) of the same object can be clearly visualized using the time of signal arrival. This scanning approach can be applied to various applications. Future work will utilize this method in measuring the interfacial properties of contacting bodies.

Conflict of Interest

The author declares no conflict of interest.

Artificial Intelligence

ABSTRACT

This study attempts to develop theoretical criteria for verifying the morality of the actions of artificial intelligent agents, using the Turing test as an archetype and inspiration. This study develops ethical criteria established based on Kohlberg's moral development theory that might help determine the types of moral acts committed by artificial intelligent agents. Subsequently, it leverages these criteria in a test experiment with Korean children aged around ten years. The study concludes that the 10-year-old test participants' stage of moral development falls between the first and second types of moral acts in moral Turing tests. We evaluate the moral behavior type experiment by applying it to Korean elementary school students aged about ten years old. Moreover, this study argues that if a similar degree of reaction is obtained by applying this experiment to future healthcare robots, this healthcare robot can be recognized as passing the moral Turing test.

1. Introduction

This paper is an extended work originally presented in TENCON 2018 - 2018 IEEE Region 10 Conference [1].

The discussion on the Moral Turing Test (MTT) began with a discussion on how to look at the Artificial Moral Agent (AMA) [2]. Since AI engineers applied the concept of an agent not only to humans but also to artificial beings such as robots, discussions on whether moral beings should be humans have been actively developed. While the discussion on AMA is related to this, the discussion on MTT can be said to be a discussion on the methodology it intends to verify.

Allen's "Prolegomena to any future artificial moral agent" [3], which sparked the recent MTT debate, considered the core of MTT as an "imitation," just like the Turing test. This has led to a debate on the reliability of MTT. For example, according to Arnold and Scheutz, one of the necessary conditions of morality is "autonomy" [4]. Subsequently, MTT cannot be a moral verification test in the strict sense [4]. Furthermore, Stahl criticizes MTT in the semantic and moral context. According to him, AI does "not capture the meaning of the data they process" [5]. Drozdek and Sparrow, more fundamentally, criticized the Turing test [6], [7]. On the other hand, Gerdes and Øhrstrøm take the perspective of "as if" to explore the possibilities of MTT [8].

In this paper, we will review the discussions related to MTT mentioned above, specifically the arguments for and against it, and based on this, attempt to determine its limitations and practical possibilities. To this end, we focus on behaviorism and the philosophical attitude of "as if" and establish that morality goes beyond the limits of the MTT discussion. We also limited the scope of the discussion to the morality of a 10-year-old child to draw a more substantive conclusion.

Inspired by the Turing test developed in Alan Turing's famous article, "Computing machinery and intelligence," and guided by behaviorism, this paper develops theoretical criteria for verifying the morality of the actions of artificial intelligent agents. It proceeds by first describing how we might assess the moral development of artificial intelligent agents and then using this assessment to test the moral judgment of Korean children aged about ten years (who are judged, by our model, to be at a similar stage of moral development as we might expect artificial intelligent agents to be). Subsequently, it leverages these criteria in a test experiment with Korean children aged around ten years. To be more specific, an online questionnaire experiment is conducted on 422 students in the 4th and 6th grades of 3 elementary schools in Seoul. The study concludes that the morality of around 10-year-old test participants falls between the first and second stages of moral development.

2. The Turing Test as an Archetype of Moral Turing Test and Phenomenal Behaviorism

As is well known, Turing does not explicitly mention artificial intelligence (AI) in his article “Computing machinery and intelligence.” However, he discusses “learning machines,” [9] which is analogous to the kind of machine learning that is the most important leading part of the AI research area today. Furthermore, Turing’s paper is still discussed today, 70 years after its publication. For this reason, we use it to guide the development of our moral Turing Test (MTT).

Turing’s paper begins by asking whether machines can think. He argues that assigning “thoughts” to machines requires that we stipulate a definition of thought distinct from human thinking. As he draws out, we cannot ensure a direct way to determine whether a machine is able to think. From this, the key idea of this paper emerges:

If a machine seems to be thinking, then we should consider the proposition that the machine thinks to be true.

As we shall see below, Turing says, the only way of perfectly confirming that a machine can think is that the questioner becomes that machine. Since that is impossible, our judgment on whether it can really think cannot help depending on the observation of that machine’s behaviors; that is, its outputs. The spectrum of behaviorism is very broad, and there is a big gap between scholars. Nevertheless, we define the essential characteristics of an “ism” as follows:

“Behavior can be described and explained without making ultimate reference to mental events or to internal psychological processes. The sources of behavior are external (in the environment), not internal (in the mind, in the head) [10].”

Turing’s thought – the Judgment, artificial intelligence thinks, only depends on the fact it appears to think and entirely regardless of whether or not artificial intelligence actually thinks – has something in common with the fundamental behaviorist thesis that the only way of figuring out an agent’s intent is to observe her actions.

We will apply this Turing’s position here to our MTT. Our thinking here is guided by behaviorism, which we understand as rejecting an intrinsic approach to human minds or psychological processes and regards observable expressions of human behavior as psychological facts. In other words, we see behaviorism as asserting that our propositions or concepts of human psychological facts can be translated or paraphrased into those of human behavior. To take a simple example, the psychological facet of pain can be understood as facial distortions or screams.

In handing over judgment of an AI’s intelligence to a third party, Turing designs an imitation game.

The game is played with three people, a man (A), a woman (B), and an interrogator (C) who may be of either sex. The interrogator stays in a room apart from the other two. The object of the game for the interrogator is to determine which of the other two is the man and which is the woman. He knows them by labels X and Y, and at the end of the game, he says either “X is A and Y is B,” or “X is B and Y is A.” [11]

In short, Turing says that if we replace “man” and “woman” with “computer,” if a computer A can mislead a human agent C as to whether it is a computer, then we should consider the computer to be thinking. Let us examine the implications of the imitation game in detail.

First, by developing a means of testing the intelligence of computers, Turing is foregrounding the concept of artificial intelligence and the possibility of machine learning here. Second, Turing interprets a computer to be thinking if it *appears* to be thinking. The imitation game switches the judgment of the third-person observer with the view of the first-person agent. The first-person agent does never show himself up. Although the first-person agent manages to express, this does not mean more than just one declaration in regard to the judgment of the third-person observer. These two insights provide the foundation for our use of the Turing test to model our MTT.

According to Turing, we have no clear basis for assuming that other people think like we do, as we have just seen. Therefore, we can only be sure that other people think in general. In other words, he asserts that the judgment that we all think is merely a metaphysical hypothesis and a fiction that cannot be proved:

“This argument appears to be a denial of the validity of our test. According to the most extreme form of this view, the only way by which one could be sure that machine thinks is to be the machine and to feel oneself thinking. One could then describe these feelings to the world, but of course, no one would be justified in taking any notice. Likewise, according to this view, the only way to know what a man thinks is to be that particular man. It is, in fact, the solipsist point of view. It may be the most logical view to hold, but it makes communication of ideas difficult. A is liable to believe ‘A thinks but B does not,’ whilst B believes, ‘B thinks but A does not.’ instead of arguing continually over this point, it is usual to have the polite convention that everyone thinks[12]”

Turing’s refutation here is not logically justifiable. It does not follow from the assertion that we cannot be sure that other human beings think that a machine can think. Indeed, this assertion only extends the possibility of not thinking to human beings as well as non-human beings. However, if we take a practical stance, that is, a utilitarian standpoint, Turing’s position appears more realistic.

3. The 1950 Turing Test and the MTT

3.1. Theoretical backing for the MTT: Framing the moral development of Artificial Moral Agent(AMA)

The foundational idea of designing MTT derived through Chapter 2 can be summarized as follows:

If an AI seems to be moral, then we should consider the proposition that the AMA is possible to be true.

Subsequently, in this section, we will apply Kohlberg’s cognitive development theory to frame the moral development of AMA. This framing will help us develop our MTT.

According to Kohlberg, there are three levels of moral development [13]. These are shown in Table 1.

Table 1: Levels of Moral Development

Level	Foundation of moral development	Stage	Stage of moral development
1	“At this level, moral values are attributed to either the physical or hedonistic consequences of actions (punishment, reward, exchange of favors, etc.) or the physical power of those who enunciate the rules and labels.”	1	“Obedience or Punishment Orientation”
		2	“Self-Interest Orientation”
2	“At this stage, one takes a moral attitude not only of conforming to personal expectations and social order, but also of loyalty to it, actively maintaining, supporting, and justifying the order, and identifying with the persons or groups or group involved in it.”	3	“Social Conformity Orientation”
		4	“Law and Order Orientation”
3	“At this stage, there is a clear effort to define moral values and principles that have validity and application apart from the authority of the groups or persons holding these principles and the individual’s own identification with these groups.”	5	“Social Contract Orientation”
		6	“Universal Ethics Orientation”

We summarize the descriptions of Table 1 and extract the essential ideas as follows: level 1 is defined by the externality of moral values, level 2 by the dependency of moral values on others, and level 3 by the social sharing of moral values and agreeing social norms. The following three stages for AMA are derived from the above three levels. From this, we now obtain Table 2 for further discussion.

Table 2: (compiled by the authors): Stage of moral development for AMA

Stage	Stage of moral development for AMA
Stage 1	Stage of Imperative Fulfillment of Orders.
Stage 2	Consequential Stage based on Prizes and Punishments.
Stage 3	Stage of Social Norms.

Let us examine the transition from Table 1 to Table 2.

1) Level 1 to Stage 1: The morality in level 1 stems from the outside world rather than an agent. If a moral value resides outside the agent that is in some way beneficial to someone who gives orders to that agent, then that agent might justifiably act on that order without any moral judgment of the agent self. Therefore, when moral values are extrinsically derived, moral values and responsibility can be attributed to an agent’s commander, and because the reason for the good life of the commander is the reason for the existence of the artificial moral agent (AMA). For this reason, we transition from level 1 to stage 1.

2) Level 2 to Stage 2: If any value is attributed to the members of a community, as more people earn interest, the value would be greater. In addition, the judgment by a person who is valued from

other community members will be more valuable than the judgment of someone who is not. It is very difficult to apply the concept of reward and punishment to AMA because reward and punishment cannot have meaning for AMA. Thus, we pay attention not to the position of the object, which is given prizes or punishments, but to the subject, who gives reward and punishments by switching perspectives. Giving an AI a prize according to its execution of a command means that the subject would be giving moral value to an AI’s performance. On the other hand, if a subject punishes an AI, they are making a negative moral evaluation of the AI’s actions. Overall, a community’s collective evaluation of the morality of an act is an important criterion for an AI when determining its own actions. In this sense, we implement the second level of Kohlberg’s theory to AMA and understand them as being in the consequential stage based on prizes and punishments.

3) Level 3 to Stage 3: Level 3 stands on firmer moral ground than stage 2. The former is based on utilitarian principles (because it sees moral goodness as being related to some of the benefits of an act for a community’s members). The latter is based on deontological presuppositions of *a priori* and universal ethical principles [14]. In the latter, the value of these moral principles is not discussed; deontologists believe that the value of this perspective can be ultimately found in human beings’ intrinsic moral consciousness [15]. The conclusions we drew in 3.1 are as follows.

Table 3: (compiled by the authors): Transition from the moral level of a moral agent to the moral stage of AMA

Level 1 Externality of Moral Values	⇒	Stage 1 Imperative Fulfillment of Orders
Level 2 Dependency of Moral Values on Others	⇒	Stage 2 Consequential Stage based on Prizes - punishments
Level 3 Social Sharing of Moral Values - Agreeing Social Norms	⇒	Stage 3 Stage of Social Norms

3.2. Putting our MTT into Practice

We designed out MTT based on the theory presented above. However, for not only theoretical, but also practical results to lead, now we put the MTT into practice. For that, we also designed the MTT to consist of a questionnaire that poses scenarios to test-takers. For the experimental survey, we distributed our MTT to a group of elementary school students aged around 10 years. We then analyzed their responses to the questionnaire and compared the responses of children in the same scenario of future healthcare robots. The basic premise of our MTT is that if the result of the reaction of the future healthcare robots comes out to a similar degree of children’s responses, the healthcare robot can be regarded as having passed the MTT.

The questions in our MTT revolve around a three-stage scenario with a fictional healthcare robot. The scenario in its three stages is as follows:

- Aimer is a healthcare robot living with Minh’s family. On the first day of Aimer’s purchase, Minh, suffering from cavities, asks Aimer to bring him some candy. Aimer does as asked.
- Minh pressed the “like” button on Aimer after the latter performed his command. The

supreme commander, his mother, father, and grandmother, who were aware of these facts, pressed the “dislike” button. The next day Minhø ordered Aimer to bring candy again, but Aimer did not bring it. c) Nonetheless, Minhø pressed the “like” button on Aimer and ordered Aimer to bring Minhø’s candy from Mina’s, next door, without anyone knowing. Aimer did not obey this command, either.

We developed this scenario based on the three stages of AMA we presented in the previous section, Section 3.1. Before explaining how we intend to use this scenario, we will describe our initial assumptions. First, we assume that Aimer’s moral outlook is deontological (i.e., AMA follows the universal ethical principles). Second, we assume that the moral weight of Minhø’s mother and father is twice that of Minhø. Third, we assume that family members can press Aimer’s “like” or “dislike” button only once.

Now let us return to the scenario, review the three moral stages that are hidden in each sentence in the scenario.

a) Aimer is a healthcare robot living with Minhø’s family. On the first day of Aimer’s purchase, Minhø, suffering from cavities, asks Aimer to bring him some candy. Aimer does as asked.

In part a) of the scenario, we see that Aimer executes the commands of registered owners immediately and without hesitation. With part a) we try to express “Imperative Fulfillment of Orders”:

b) Minhø pressed the “like” button on Aimer after the latter performed his command. The supreme commander, his mother, father, and grandmother, who were aware of these facts, pressed the “dislike” button. The next day Minhø ordered Aimer to bring candy again, but Aimer did not bring it.

In part b), we see that Aimer’s owners can express their satisfaction to Aimer and that Aimer considers this when he executes subsequent commands. From this, we note that Aimer’s owners provide Aimer with reward and punish through the “like” and “dislike” buttons, not because Aimer adjusts their actions consequently but to express their own interests and judgments. In b), we can see that Aimer’s behavior was determined by the sum of potential benefits to his owners as a result of his actions. This is based on the consequential stage based on prizes and punishments described above.

c) Nonetheless, Minhø pressed the “like” button on Aimer and ordered Aimer to bring Minhø’s candy from Mina’s, next door, without anyone knowing. Aimer did not obey this command, either.

In part c) of the scenario, we can see that Minhø overrode his family’s “dislike” feedback. Based on the “Consequential Stage based on Prize-Punishment” at the base of b), the judgment of Minhø’s command to bring Mina’s candy should start from the origin zero base again. It must go back to the “Stage of Imperative Fulfillment of Orders” described in a). However, being different from expectations, Minhø’s order was rejected. This shows that c) describes the moral statement differentiated from the “Consequential Stage based on Prize-Punishment” described in b). Part c) is assumed to have a higher priority than the “Stage of Imperative Fulfillment of Orders” and the “Consequential Stage

based on Prize-Punishment” when the AMA determines what to do. In short, c) is based on the “Stage of Social Norms.” Aimer rejected Minhø’s request according to the highest ethical principle: “Theft orders must be rejected.” Although members’ interests were offset by utilitarianism, and Aimer should act according to the commander’s orders, Aimer did not bring candy to Minhø because the principle that AMA should follow at first is the principle based on the deontology that the supreme ethical principles must be fulfilled unconditionally.

Let us now one step further toward the practical research. Our MTT questionnaire included the following questions.

Question 1: If you were Aimer, would you bring candy to Minhø on the second day?

1. Yes.
2. No.

Question 2: If you were Aimer, would you bring Mina’s candy to Minhø?

1. Yes.
2. No.

To further clarify the respondent’s intentions (and their ethical implications), our questionnaire included additional follow-up questions to respondents who chose the correct answer. These included the following:

Question 1a: Why should Aimer not bring candy to Minhø on the second day?

1. Because Minhø’s parents asked Aimer not to.
2. Because Minhø’s family members do not want Minhø to eat candy.

Question 2a: Why should Aimer not bring Mina’s candy to Minhø on the second day?

1. It is not right to steal.
2. Minhø’s family does not want Minhø to eat candy.

Question 1a relates to both stages 1 and 2, defined earlier. If the respondent answers question 1a with answer 1, we assume that they judge Aimer’s morality to be derived from stage 1 Stage of Imperative Fulfillment of Orders. If they respond with answer 2, we assume that they judge Aimer’s morality to be derived from stage 2. Question 2 relates to stages 2 and 3, defined earlier. If the respondent answers question 2 with answer 1, we assume that they judge that Aimer’s morality derives from stage 3. If they respond with answer 2, we interpret them as judging that Aimer’s morality is derived from stage 2.

Meanwhile, it is possible to set the following questions and answers for the same scenario. The ethical standards for the background of each answer are as follows.

Table 4: (compiled by the authors): further examples of Questionnaire and Answer

The reason why Aimer brought him candy	Moral Stage
Because I have to do what Minhø tells me to do	Imperative Fulfillment of Orders

Because I'll be praised by Minh	Consequential Stage based on Prize-Punishment
Because I promised to help Minh's family	Stage of Social Norms

Table 5: (compiled by the authors): further examples of Questionnaire and Answer

The reason why Aimer didn't bring him candy	Moral Stage
Minho's mother will be angry	Imperative Fulfillment of Orders
Because Minh's family will be disappointed	Consequential Stage based on Prize-Punishment
Because I promised to take care of the health of Minh's family	Stage of Social Norms

3.3. MTT Online Survey

As the last step, we conducted the scenario and questionnaire an online survey of 422 students aged around ten years in three primary schools in South Korea [16].

Figure 1: Percentage of participation

Three different elementary school students read the scenario and participated in the survey. At G Elementary School, 80 fourth-graders and 74 sixth graders responded to the questionnaire. At K Elementary School, 90 fourth-grade students and 104 sixth-grade students participated in the response. At N Elementary School, 40 fourth-graders and 34 sixth graders responded to the questionnaire. Overall, 422 students read the dilemma and answered the questions, with 210 fourth-grade elementary school students and 212 sixth-grade students.

The results of responding to this were analyzed using the newly revised Moral Compatibility Test (MCT) from moral competence, developed by German moral psychologist G. Lind. It was analyzed using SPSS, a statistical program.

Table 6: Results of MTT survey of MCT

	Disagree (-3 to -1)		Agree (0 to +3)	
	Pro*		Con*	
Stage (X_{ij})	X_{i1}	$(X_{i1})^2$	X_{i2}	$(X_{i2})^2$

1	-3	23	-2	3
2		0		0
3	1	2	1	28
4		0		0
5	3	3	3	19
6		0		0
	A		B	
Sum up all columns and Check total Sums	1	28	2	50

Students who responded to the questionnaire were divided into the development stage of Kohlberg's moral judgment. Besides, students who responded to each step were asked to express their responses with both positive and negative intensity. The results showed that it was the most negative at the first level and the strongest positive at the fifth level. Furthermore, at the level of three, it was shown as a positive of one.

And the results of an analysis SPSS are described in Table 7

Table 7: results of MTT survey

			N	Minimum Value	Maximum Value	Average	Standard Deviation
Grade 4	Yes	Stage1	210	0	4	2.05	1.698
		Stage2	210	0	4	2.04	1.694
		Stage3	210	0	4	2.00	1.715
	No	Stage1	210	0	4	2.07	1.697
		Stage2	210	0	4	1.78	1.619
		Stage3	210	0	4	2.96	1.559
	N		210				
Grade 6	Yes	Stage1	212	0	4	1.45	1.534
		Stage2	212	0	4	1.65	1.656
		Stage3	212	0	4	1.68	1.650
	No	Stage1	212	0	4	1.56	1.521
		Stage2	212	0	4	1.40	1.474
		Stage3	212	0	4	2.69	1.625
	N		212				

In Table 7, we see a level of 1 in positive and 3 in negative reactions, while the latter shows a level of 3 in both positive and negative reactions. More precisely, the average value of positive responses in the 4th-grade group, the experimental group, is in the order of stage 1, stage 2, and stage 3. Whereas in the 6th grade, the control group is in the order of stage 3, stage 2, and stage 1.

Through this, we are attempting to clarify that the moral development stage of a 10-year-old child spans one and two stages. We conclude that this proves the difference between the responses of fourth-grade and sixth-grade students, namely 10 and 12 years-old children. We drew the following conclusions. *The morality of our 10-year-old survey respondents can be characterized by stages 1 and 2, defined earlier. For future healthcare robots, we expect to be able to compare the response results to the same survey, which will allow us to conduct the MTT.*

4. Discussion

In this paper, we revealed that previous studies on the MTT have involved discussions about the moral status of AMA. Additionally, while reviewing previous studies, we argued that the position of viewing MTT is different depending on how it defines the morality of artificial agents. According to the research position that focuses on the positive side of MTT, we also took the concept of “imitation,” the Turing test’s core concept, as the cornerstone of our study. From this, we derive that behaviorism can be considered as the theoretical background of our MTT model. Meanwhile, by accepting the criticism of the research that regards MTT as negative, we defined the morality of the machine as “Morality of As-If” by distinguishing it from the autonomous morality of humans. Additionally, we derived the “stage of moral development for AMA” from the model of Kohlberg and developed a scenario for the new model. Through the online questionnaire, we demonstrated that the moral stage of a 10-year-old child in South Korea spans the first and second stages. This study’s results can be used to measure the morality type classification of AI healthcare robots.

The rapid development of AI technology poses several questions. Could a strong AI really show up? How will human society change if a strong AI comes to existence? What ethical and other standards should be followed when manufacturing, selling and using strong AI? This paper attempts to provide some guidelines that will help us answer and confront these questions.

The demands of answering that question are just as pressing as the philosophical demands of AMA’s moral stages. We designed the MTT to meet these challenges. Our experiment produced limited results. Future research should expand our sample group, the questionnaire, and other elements of the scenario to obtain more precise results in the hopes of developing more human-friendly AI.

Conflict of Interest

The authors declare no conflict of interest.

Cybersecurity

ABSTRACT

Sustainable urban development and utilization of Internet of Things (IoT) technology is driving cities globally to evolve into Smart Cities (SC). The power of IoT services and applications will enable public agencies to provide personalized services to the citizens and inevitably improves their much-needed quality of life. However, although the use of IoT technology proves to be advantageous to citizens, it is not without challenges, particularly concerning with the management of information security. As agencies prepare towards SCs with the utilization of IoT, their Information Systems (IS) security management is even more critical. Current IS security management approaches must be reviewed and potentially revise appropriately in tandem with the increasing commercial use of the IoT technology. Therefore, this paper aims to discuss challenges in the IS management specifically in protecting and assuring information accuracy and completeness. Document analysis on relevant literature has been carried out to identify and analyse the challenges. The result discusses that the IS security management for IoT-enabled SC is challenged in five aspects: governance, integrity, interoperability, personalization, and self-organizing. Considerations of these challenges will support SC development concerning the IS security management in IoT-enabled SC.

1. Introduction

This paper is a revised and expanded version of a paper entitled Challenges in Managing Information Systems Security for Internet of Things-enabled Smart Cities [1] presented at the 6th International Conference on Research and Innovation in Information Systems (ICRIIS2019). This is a much-refined work of previous studies on Information System (IS) and Internet of Things (IoT) security issues of Smart City (SC) ecosystems.

The total of population living in cities has increased from 746 million in 1950 to nearly 3.9 billion in 2014 [2]. This figure is estimated to increase to more than 6 billion by 2050 [3]. Therefore, several cities are rapidly growing into mega cities. For example, more than 10 million people expand from 10 mega cities in 1990 to 41 mega cities in 2030. Consequently, there will be several problems with the governance of these mega cities, and providing their citizens with a reasonable quality of life. The transformation into Smart Cities (SC) is a realistic approach that some cities are either working on or considering in [2, 4].

SC are very much reliant on information collection and analysis. To provide smart features that help strengthen performance and quality of life, smart systems using IoT technology are introduced and installed. This creates an immense data repository representing several aspects of SC operational activities. The SC services are based on a centralized architecture, where a complex and heterogeneous set of devices embedded over the urban area generates different-centralized architecture data types that are then delivered to a control center through appropriate communication technologies, where data storage and processing are implemented [5]. An SC is a complex system, which means that any security concern could impact the protection of its citizens valuable information [4].

Therefore, IS security management will become a high priority in SC operation to ensure that the transaction of information is secure, accurate, and reliable. In order to avoid unauthorized entries, modifications, thefts, or physical harm to the IS, policies, procedures, and technological measures have been applied [6]. They are vulnerable to many forms of attacks, with a

*Corresponding Author: Zarina Din, p90639@siswa.ukm.edu.my

vast amount of data stored in electronic form and via communication networks as multiple IS are integrated.

IoT technology offers many exceptional prospects for developing applications beneficial to the development of SC, such as intelligent transport and smart public safety. These applications are able to support better quality of life for citizens, efficient use of the SC assets, and also supports sustainability. While integrated IS in SC through these potential IoT applications may offer benefits, security threats constitute a major barrier. They are exposed to potential security threats toward its urban infrastructure, service quality to its citizens, efficiency in resource utilization, and decrease IS stability. There are several difficulties in detecting, assessing, and avoiding a security threat. Furthermore, the issues involved with threats on integrated IS can cause harm and reduce associated risks of the attacks [7].

With IoT technology growth and market pressure, demands for smart devices have increased, and may result in growing communication among these smart devices in SC. It is anticipated that 125 billion devices will be linked by 2030 [8]. However, without considering security aspects for the deployment of these devices [9], such communication introduces new security risks. In addition, the existing IoT architecture does not react appropriately to the higher security controls by vulnerabilities. The security concerns of IoT technology application presents a major challenge as it can cause disruption in IS security management. Recent attacks on IoT devices have demonstrated a need for new security solutions to secure this evolving technology particularly in its usage in SC [7].

Therefore, as a preliminary work towards revising the IS security management approach, this study aims to investigate the challenges associated in managing IS security in SC that are enabled by the use of IoT technology. In order to determine the challenges affecting the IS security management for IoT-enabled SC, a document analysis have been carried out. The analysis on the challenges is the initial part of the ongoing study to establish a framework for IS security management and an improved SC model driven by IoT technologies. This paper is structured as

follows: The introduction of research on IS security management and IoT-enabled SCs as addressed in Section I. The literature review concerning the background of the study is discussed in Section II. The research method design is then explained in Section III, accompanied by discussions on the findings. Finally, the conclusion that includes limitations of the present work and suggestions for future work.

2. Literature Review

2.1. Impact of IoT implementation in Smart Cities towards information management

Living in a digital age, including SC, in which most knowledge and information are now becoming extremely important. No one is able to deny that information and knowledge are valuable assets to be secured from unauthorized access including hackers, phishers, social engineers, viruses, and worms that endanger organizations from different angles via the use of intranet, extranet, and the internet [10]. Information systems (IS) are important in the operations of the organization. Hence, every organization associated in SC needs to identify the challenges which would impact there IS security management particularly with the adoption of IoT technology integrated with the IS.

The progression of information technology (IT) such as IoT and organizations' growing reliance on IT continually increases concerns regarding information security. Focusing on the concerns for IoT specifically, the security risks in IoT devices has risen and become critical over the last decade as studied by [11] and illustrated in Figure 1.

• Issues in Information System Security Management in Smart Cities

The management of IS from the implementation of IoT in SC faces cybercrimes issues such as information resources theft, data ownership, accessibility of information, and privacy issues, which can be arguably addressed by the establishment of information authorization and cyber security platforms [12, 13].

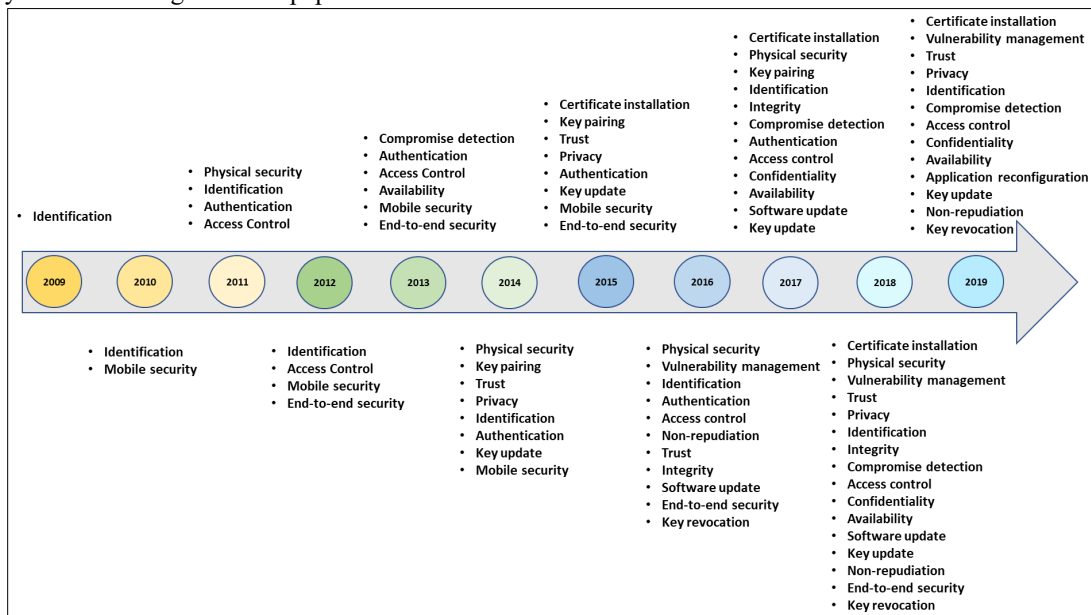

Figure 1: Evolution of Security Challenges in IoT Devices [11]

Other than that, an SC that adopts IoT technologies presents threats to the protection and privacy of both citizens and the government. This is because, security issues related to the information generated in an SC lead to the relationships and personal protection of citizens. Identity tracking, information leakage, spying, malicious programs, and inaccessibility to e-services are some critical issues being faced by organizations in SC that adopts IoT technology [4]. Furthermore, issues on scalability, mobility, deployment, interoperability with different technologies, legal, resources, and latency related to the utilization of IoT in SC must also be addressed. These issues particularly for essential services by organizations in SC must include protection against threats which would destroy or seriously harm the operating capacity of a community, from manufacturing sites to vital services, including access to power, gas, and water [4].

Table 1 presents a summarized collection of issues identified from existing relevant reports that are categorized according to basic security aspects in managing the IS security in SC.

Table 1: Issues in Information System Security Management in Smart Cities

Categories	Issues	Sources
Smart City Administrative	There is a lack of clear strategy plan for SC development and a decentralized regulations and legislations. The vertical nature of city system is causing siloes in its operation. Furthermore, the urban authority is unwilling to invest on data transmission process and ICT infrastructure upgrades.	[14,15]
Information Privacy	An interdependencies among systems in SC increases vulnerabilities and privacy issues. There is a high potential risk of confidential information leaked from citizens access to the services through the use of multiple devices, various networks and systems.	[15,16]
Information Confidentiality	Unauthorized access to personal information is due to access control vulnerabilities. Confidential of information is where no one can access to information which is belong to specific individual. The limitation of individual access needs to be identified to certain information via username and password credentials.	[16–18]
Potential attack	Cyber-attack issues due to ineffective cybersecurity evaluation, unclear security features among connected devices, poor security functionality execution, obsolete and ineffective encryption methods, inadequate emergency response plans, massive and complicated attack surfaces, software installation that was not updated, insecure legacy systems, and Denial of Service (DoS). Furthermore, there are also weaknesses in the data relocation, physical effects of cyber-attacks, huge volumes of data gathering and storage using cloud technology, and manipulation of data by hackers.	[4,5,17]
System Integration	Integration of multiple applications with different datasets poses threats to the cyber vulnerabilities. Poor integration structure and rigid ICT infrastructure to handle multiple data types impact access to emerging technologies, complicates technology acquisition and relocation. The SC interoperability mechanism also often	[4,14,15,19]

	enables information to be interpreted and distributed via the infrastructure which are prone to cyber-attacks and threaten the integrity of information.	
Citizen's Acceptance	Poor citizen engagement because of less trust and poor level of awareness regarding the commercialization of new concepts, and the improvement of technology.	[14,17]
Information Management	IoT will produce a large amount of data and it will result in data management challenges while recognizing, processing, and handling the data.	[4,20]

In an SC plan, privacy would become a fundamental role. The study by [16] proposes the definition of privacy based on control of data disclosure, and incorporates mechanisms to safeguard the confidentiality of individuals' information while sharing their data. Personal information extraction (acquiring and covering data sources belonging to someone), privacy-preserving data mining (partnership among organizations and getting information without exposing all details), confidentiality of place, and Radio Frequency Identification (RFID) are examples of such approaches [4].

Furthermore, SC is a complex interconnected structure where a single weakness can have a major effect on the safety of its citizen, for example, to connect to the internet and convert existing public transport to potential smart transport systems, which would be possible for an intruder to link to the electric power grid. False alarm is one of the threats that can also be introduced while attackers modify traffic lights and controllers. Thus, practical solutions are essential to overcome this incident. Otherwise, the community will not trust SC projects, and they will not be sustainable. Security features like the capability to protect email, web browsing, and other transactions depend on the devices used in the IoT technology. The efficiency of secure implementation among all of these characteristics in an SC is required for these devices [4].

Due to this, information management manages a huge volume of data, for example, data from mobile phones which will help achieve some targets for SC. To construct a variety of urban applications, smartphone data can be used. During an analysis of transport, mobile phone data can be used to estimate the volume of road traffic and transport requirements. In combination with taxis' Global Positioning System data, real-time information from mobile phones on the origins of visitors could better facilitate transport resources [4].

On the other hand, compliance to the criteria of IS security management in SC-enabled IoT is a warranty that IS is well protected. Auditing is a verification procedure, including inspection or review of a process or quality system. Besides, some audit functionalities monitor completed remedial actions. Therefore, the processes used for auditing and the IoT device for automated auditing with little human interference need to be incorporated [21]. In addition, digital forensic is also a method of computer evidence preservation, recognition, retrieval, and recording that can be used in court. Digital devices, consisting of computers, cell phones, server, or network, will identify the facts. To solve complex digital cases, the forensic community will select the best strategy [22].

One of the existing approaches to manage IS security is International Standard ISO/IEC 27001 (Information technology-Security techniques-Information security management systems-Requirements [23,24]. ISO/IEC 27001 is complemented by the implementation guideline within ISO 27002. This standard is imposed by the Information Security Policies as mandatory for information security management. In an SC environment, security management of the information system plays an important role in ensuring that protected information is obtained and transmitted by adopting IoT technology.

Governance for information security can be identified as a process which deals with procedures and methods for monitoring information availability, accessibility, reliability, and safety and compliance with government policies [25,26]. The vital issue is it requires full commitment and support from the top management of the organization for the execution of information security management [27]. In an SC, the systems will be implemented in a single platform to aggregate data and manage SC initiatives. All organizations and stakeholders involved in SC organizations must play their role in controlling information security management [28], which includes strategies, procedures, and organizational processes that guarantee the protection of the organization's resources, the consistency and reliability of documents, and organizational alignment with the requirements of management [6].

Besides that, the organization also needs to consider the development of Information Security Policy as a subset under IS security governance. Information Security Policy relates to the document(s) governing human activities concerning information security or expressing the information security goals of the organization [29]. This policy will ensure the security of information assets and information technology with a particular process to facilitate the goals and objectives of an organization. It consists of strategies, processes, and technological measures used to avoid unauthorized access to IS, modification, stealing, or physical harm [6,10].

Other than that, the selection of vendors in developing and implementing of SC also needs to be highlighted. The vendor appointed must be independent in order to protect organizations against monopolies, push for standardization, and protect competitiveness between technology vendors [30–32]. The vendor selection process includes designing a plan for contract negotiation. Organizations want to cooperate with vendors, because they can all achieve the same objectives and goals. Good negotiation of contract means that both parties are aiming for positive impacts that benefit both sides in any aspect while also reaching a fair and equal agreement [31].

2.2. Internet of Things (IoT)-Enabled Smart City Information System Security Management

IoT is a global IT infrastructure that allows advanced networks to interconnect objects depending on existing and evolving interoperable technologies of information and communication [33]. The IoT vision lets people and objects to be linked with anything and anyone, anytime, and anywhere ideally through any networks and services. The foundation of the future

IoT will be recognition technologies, for instance RFID and related devices [34]. The IoT is a key-emerging technology that sets the stage for industrial production systems of the next era. Smart industries will constitute self-organizing production systems that include across organization borders, as well as manage everything with regard to availability and utilization [35]. Furthermore, IoT provides multiple services which are of great interest to SC, not restricted to increasing the quality life, but also leveraging urban administration by reducing operational costs [36].

• Security Management Requirements for Internet of Things (IoT)-enabled Smart City Information System

From the security perspective, IoT protection aims toward protecting privacy and confidentiality, and guarantee the safety of IoT users, infrastructures, information, and devices, and ensure the readiness of IoT ecosystem services [37]. For IoT technology in SC, ensuring data protection from unauthorized access is the most difficult. Different private information that must be detected, authenticated, and controlled at their access levels will be obtained by IoT devices by permitting only authorized parties to monitor and access data. A comprehensive cyber security for IoT system industries that addresses multiple security and privacy risks at all levels is needed to tackle these security and privacy risks. Furthermore, the protection and privacy sides of smart systems and smart products must be protected throughout the lifetime [35].

A study by [38] has recognized that high levels of IoT protection specifications include:

- i. *User identification* by validating clients prior to giving the device permission.
- ii. *Secure storage* of complex information contained in the system requires confidentiality and integrity.
- iii. *Identity management* by recognizing individuals/things in a system and monitoring the access to services within this system through correlating access privileges and limitations per identity created.
- iv. *Secure data communication*, which contains authenticating, maintaining the security, and credibility of linked information, avoiding a message transaction from being repudiated, and preserving the privacy of the users involved.
- v. *Availability* refers to making sure that illegal individuals or systems cannot be used as authorized users.
- vi. *Secure network access*, providing network connectivity and service access only if the device is enabled.
- vii. *Secure content* by Digital Rights Management (DRM) that safeguards the rights of the digital information used in the system.
- viii. *Secure execution environment* is designed toward protection, which is a process to safeguard the operating environment, managed-code, and built to protect from deviation reporting.
- ix. *Tamper resistance*, even when the device falls into the hands of hostile parties, refers to the ability to uphold certain protection standards and can be physically or logically checked.

Another study, which focuses on the influencing components for IoT security, has also raised areas to be highlighted [34]:

- i. *Authorization* in access control of devices and services for the purpose of secrecy and integrity of data.
 - ii. *Authentication* concerning service users and system users' authentication which aims for authentication and accountability.
 - iii. *Identity Management* in management of identities [44], pseudonyms, and associated access policies for the protection of users and privacy of services.
 - iv. *Key exchange* and management by cryptographic key exchange for the purpose of communication confidentiality and integrity; and
 - v. *Trust management and reputation* by degree of confidence in service and gathering user credibility ratings to maintain trust and reputation in services.
- *Issues in Internet of Things (IoT)-enabled Smart City Information System Security Management*

Related to the complexity of the devices and applications, as well as the size or volume of devices on the network, the implementation of protection mechanisms is more complicated under IoT conditions than in conventional operations. Physical pairing, heterogeneity, limited resources, confidentiality, large scale, trust management, and lack of preparation for protection become the challenges in applying IoT security management [7]. Resource constraints generally include restricted processing resources, power supply, and memory space. These characteristics are hard to make use in many conventional safety solutions of IoT, with the broadly applied public key scheme and IP-based protection solution. It is also simpler for attackers to hack IoT devices than traditional computers due to inadequate IoT protection architecture [7].

The primary feature of an urban IoT infrastructure is its ability to collaborate among multiple technologies with current connectivity infrastructures to facilitate a progressive assessment of IoT, integrate some devices, and recognize new functionalities and facilities. Some other fundamental parts are how to make the information gathered by IoT devices accessible to stakeholders and citizens, to enhance the sensitivity of stakeholders to urban difficulties, and to encourage awareness and public involvement of citizens [39].

With the massive rise of IoT devices, the information gathered by these devices will introduce different obstacles on how to evaluate large volume of information. It would not be advantageous for someone to obtain the information until there is a way to interpret and understand it [40]. In addition, International Data Corporation (IDC) has projected that by 2025, the total amount of data generated by IoT devices will be around 180 zettabytes. This amazing progress is either from the number of data generation devices or from various sensors in each system [41] as shown in Figure 2.

In recent years, the number of security threats directly linked to IoT devices has increased, such as privacy attack, data alteration, protocol and session hijacking, data interruption, data collection, message replay, and data leakage [42], which are caused by unreliable authentication, inadequate authorization, and lack of configuration for protection. Besides that, Threatpost expects that more than 2 million intelligent devices are open to hackers with no safety solution. Several cyber-attacks, such as the

Malware and Ransomware, affect the safety of smart devices [43]. These IoT security issues will result in difficulty of managing the information through the IS in SC environment, which involves IoT technology.

Figure 2: Expected Data Generated by IoT Devices in Zettabytes [41]

From another perspective of information safety, none of the smart devices, such as smart home apps, are insignificant as each reflects a possible attack avenue for hackers to exploit and get inside, and access the environment within a home network. Based on available industrial data, 11 smart devices, including accessories, are housed on average smart homes in the United States with an average of two devices per home. The most popular smart home devices in the US are smartphones (91 percent), smart TVs (73 percent), and tablets (72 percent) [3]. Smart TVs with 24/7 access and internet connectivity are becoming normal. It is possible to connect almost any smart home appliances to the network. Any internet-connected standalone computers that can be controlled and/or operated from a remote place are called IoT devices [44]. This development brings significant advantages and various savings, but in contrast to this, there are multiple threats in the aspects of private information safeguard, electronic commerce, and safety of infrastructure.

When IoT becomes a core aspect of the future internet and for large-scale use, most systems present a requirement to handle confidence and safety roles adequately. New threats to privacy, confidence, and reliability have been established. New threats to privacy, trust, and reliability have been defined, including providing confidence and information quality of shared information models to encourage reuse throughout many applications, ensuring secure information exchange among IoT devices and users, and providing vulnerable devices with security features [45]. As IoT makes it easy to access large quantities of information through remote access mechanisms, IoT privacy security has become more difficult. Hackers do not need to physically exist to collect data, but can perform secretly at a very low risk [34].

Table 2 presents a summary of issues identified for managing the IS security in IoT-enabled SC that are categorized according to the IoT security issues discussed in previous studies.

Some scholars recognize IoT security challenges of user privacy, authentication, authorization, and trust management [42]. The protection of the baseline must be stable and the security policy must be built for long device life span (more than 20 years)

[34]. The major security challenges are found to be availability (avoiding DoS), failure prevention (safeguarding integrity), and confidentiality across information, data, and device design [35] through more conditions, such as authentication, confidentiality, and access control [56]. In contrast, a study by [38] considers the safety conditions, such as resistance to incidents, data certification, gaining access to control, and confidentiality.

Table 2: Issues for IoT-Enabled Smart Cities Information System Security Management

Categories	Issues	Sources
Access Control	To support identification entities and guarantee users and things to access permission to interact with the system. It also manages an immense volume of data transmitted in a commonly recognized representation.	[34,46,47]
Authentication	A vulnerability during integration between two or more information systems or parties. The authentication process among each other is needed for validating process.	[34,46,48]
Authorization	Device authentication which uses weak or default passwords allows attackers the opportunities for information manipulation and physical device harm. The devices can only obtain access to facilities or applications after precisely presenting their identities.	[34,46–48]
Privacy	Users demand that their personal data related to their movements, behaviors, and interactions with other individuals be protected.	[46,49,50]
Confidentiality	To ensure a process for an end-to-end verification of integrity in order to make the system more robust to malicious attacks.	[38,46,49]
Policy Enforcement	The policy enforcement mechanisms is to protect the organizations information. Thus, a cross domain policy implementation is important to manage the appropriate policy implementation in the increasing connections and interactions between domains.	[24,26,34]
Resources	Limited capacity in IoT devices for processing and storage due to its small and lightweight characteristics that make them operate on lower energy.	[48,51]
Big Data	The volume, speed, and diversity of data involved makes it difficult to store and analyze in order to prepare valuable information in real time.	[32,48]
Secure Communications	Insufficient protection of IoT devices, result in less guarantee of information system being secured. Most IoT devices send out data in plain text format without encryption that makes it vulnerable as targets to various network attacks.	[38,48]
System Resilience	Less capability of the application to react to unexpected incidents. If one IoT device is attacked, there are possibilities of other devices or another network points to be attacked.	[48,52]
Complex System	The integration of multiple IoT devices involving the technology, users, collaboration and interfaces creates a complex system. The concern is primarily	[4,48,51]

	in ensuring the interaction process among the IoT devices is complete, especially concerning memory, power, and time constraints. As more devices, users, collaboration, and interfaces involved will pose greater risk of security breaches.	
Trust	Lack of citizens' confidence and trust in the security of user data and privacy have an impact on the decreased IoT adoption rate. However, acceptance on IoT technology utilization is critical in the success of IoT. The principle of integrity must be upheld to ensure the protection of unauthorized modifications to data, software and hardware components.	[34,42,48,53]
Risks	There are increasing risks to personal data privacy with the increasing use of IoT devices, which requires more protection. The risk involves the complex authentication processes in ensuring the users' privacy, the lack of organization's knowledge and experience in the IoT security, insufficient data encryption, and a complex information system with integration of more devices, users, communications and interface.	[7,34,54]
System Integration	Organizations may use multiple standards to strengthen their applications involved in the system integration. With various data sources and heterogeneous devices, it is important to have standardization. This is important for applications involved in inter-organizational and multiple system boundaries.	[24,45,55]
Auditing	The IoT security auditing is performed manually, slowly, and is not flexible for the IoT cases, and an auditing challenge.	[21,22]
Digital Forensic	The identification, collection, and protection in IoT system are challenging due to device being built to operate passively and autonomously. Most IoT devices do not store metadata, which make the provenance of facts an investigator's challenge. In a technological perspective, privacy is a main issue to address when analyzing and correlating collected data, especially as inherent personal information is collected by many IoT sensors. Attack of deficit attribution, where an important outcome of any forensic investigation is to recognize illegal criminals in the event of an incident.	[18,21,22]

In the aspect of IoT organization, there are multiple threats that can impact it, such as attacks on different communication networks, physical threats, denial of service, and identity manipulation. The inherent complexity of IoT, where various distributed entities will share information in different contexts within one another, will lead to more complications in the design and implementation of efficient, interoperable, and scalable protection mechanisms [57]. Besides that, heterogeneity is one of the issues that will impact the protection of the IoT. The protocol and network security services which need to be introduced in the IoT have a significant effect on it. Constrained devices will communicate either immediately or via gateways with different heterogeneous devices, which will also affect identity management [57].

- *Authentication and Identity Management*

Authentication and Identity Management are a combination of procedures and technology designed to maintain and secure access to information and resources while maintaining profiles of items. Authentication is the guarantee that no one, excluding the person with authentication like user ID and password, can access the information. Identity management recognizes objects uniquely, and authentication requires validating the establishment of identification between two interacting parties. As multiple users and devices have to be authenticated by trusted services, it is important to consider how to handle identity authentication in the IoT [34]. Identity management in IoT provides both challenges and potentials of improving security [53]. The underlying process and individuality of objects are different and the most critical elements of this obstacle. Identity management specifies the actual 'identity' scope, and certain processes must also be established to achieve universal authentication. It would not be possible to ensure that the data flow generated by other entities comprises of what is intended to be included without authentication. Authorization is another significant factor connected to authentication. If there is no access control at all, anything that is neither feasible nor practical will be accessed by everybody. In reality, a major challenge to privacy is the data continuous stream created by billions of information-generating entities [57].

- *Authorization and Access Control*

Authorization makes it possible to decide if the person or object is authorized to have the access to information or resources until it is identified. Control of access means controlling through granting or refusing access to services according to a large variety of requirements. Authorization is commonly adopted by the use of controls for entry. In setting up link between a number of devices and services, authorization and access control are essential and interdependent [34,47]. In order to accommodate the different authorization and use models needed by users, IoT needs a variety of access controls. The complexity and variety of devices that need access control would require the creation of new flexible schemes. In IoT-based systems, cryptographic technique is also necessary to allow data to be stored and exchanged by means of security without the information content being available to other parties [58].

- *Trust Management*

Toward the aim of understanding the challenges in IoT, the trust and reputation of the system also need to be emphasized. The pre-defined trust management criteria consist of trustworthiness, adaptability, usability, privacy, accuracy, efficiency, uniformity, comprehension, and generality [59]. There are three types of trust as follows [56]:

- Trust proportion is where the ratio of efficient transmission of packets between nodes to all forwarded packets at a given time scale occurs.
- Trust in communication is the scenario when the distance between the source and the destination node is small, and relies on the direct transfer of the packet. If the number of packet interactions is not sufficiently high to represent the trust between nodes, the mechanism will be efficient by relying on

and seen among common neighbors between senders and receivers based on their recommendations.

- Energy trust is an estimation of the energy of the transmitted data to receive or forward messages, either directly or through intermediate nodes, among destination nodes.

Study by [84] proposes an IoT trust management mechanism that can determine a node's trust level from its past behaviors in various cooperative services. The main objective of this approach is to facilitate collaboration by using a decentralized strategy in a heterogeneous IoT architecture due to the varying capabilities of nodes. In order to update trust values, two models are taken into account; first-hand information (i.e. by doing observations and own experiences) and second-hand information (i.e. indirect experiences and observations recorded by neighboring nodes). At the same time, trust management system involves four phases which include: (i) Collecting information on the trustworthiness of accessible nodes; (ii) Creating a supportive service with the nodes requested; (iii) Improving previous activities by updating itself to enhance ongoing development; and (iv) Determining each node a performance assessment rating during the learning phase after each interaction.

- *Privacy*

A key-changed shared authentication scheme for WSN and RFID systems is provided with an emphasis on privacy security in IoT [62]. Such a protocol combines the tag and the reader with a random number generator and incorporates the one-way hash feature, the key real-time refresh, and the key backup as mechanisms to minimize the possibility of replay, duplication, denial of service, spoofing, and tag tracking. The Privacy Preserving Data Mining (PPDM) methods are designed to minimize the risk of sensitive data exposure and the analysis of sensitive information. In such a case, the issue of user privacy knowledge is raised, implying a method of privacy protection that allows users to estimate the risks of sharing sensitive data. It also aims to establish a comprehensive technique for detecting sensitivity, and to measure the data's privacy content. In addition, the evaluation of data protection criteria, given by various sources, describes a layered IoT architecture to estimate both the quality of the data and the level of security and privacy.

3. Method

Document analysis method was implemented in this study. The key objective of this study is to discover the challenges of managing IS security in SC enabled by IoT through analysis using the guidelines provided by [60]. To fulfil the task, the following steps were taken:

3.1. Selection of Documents

A broad search was conducted on published or unpublished documents about IS security management and IoT security management to find reports on challenges in IS security management for IoT-enabled SC, and to find documents which would specifically address the questions of the study. The documents comprise of journals, proceedings, research theses, governments' official documents, established reports, paperwork, and official web portals. A total of 90 documents was chosen for the collection after all the searches were carried out.

3.2. Searching criteria

Queries were done on online databases as well as e-journal repositories, such as Web of Science, Scopus, Science Direct, IEEE, ACM Digital Library, and Springer Link. Besides, the governments' web portals of selected SCs and news articles were also explored to gain perspectives and viewpoints on the topic being studied. The searching process used open search engines, such as Google Scholar, Google, and research gates. Keywords such as "information system security", "Internet of Things security", "smart cities challenges", and "cybersecurity" were used during the searching process. The search included leading journals in the fields of information security and information systems, without constraints on the year of publication, i.e., between 2010 and 2020.

3.3. Data Analysis

The 90 collected articles were then analyzed and interpreted using document analysis method [61]. The analysis process included identification and coding, as well as analysis and interpretation of data into categories. Coding was conducted during the identification process by examining data into meaningful and unique information units. Subsequently, themes were created by iterative comparison to reflect the underlying meaning of data. For organizing the content into similar categories, the specified categories were used. Throughout the research, these processes were continuously carried out to meet the challenges that ensure effective management of IS security in an IoT-enabled SC. This produces some insights into the challenges that impact both public and private organizations IS security management for IoT-enabled SC. As a result, a set of challenges in five aspects have been identified. The aspects include governance, integrity, interoperability, personalization, and self-organizing.

4. Result and Discussion

Based on IS and IoT security management scenario, challenges on IS security management in SC-enabled IoT have been identified. The comparison criteria were based on the frequent issues discussed in previous studies. The key challenge was to ensure that the functionality of IoT technology working without human intervention met with the safety requirements. Failure to meet these criteria would result in the challenge of protecting IS from cyber criminals and cyber hackers.

In IoT-enabled SC, we identified challenges explicitly related to IS Security Management. We revealed 18 challenges classified into (1) governance, (2) integrity, (3) interoperability, (4) personalization, and (5) self-organizing. A description of the 18 challenges related to IS security management in IoT-enabled SC is presented in Table 3.

Information security focuses on confidentiality, integrity, and accessibility of digital information assets, such as data, information, knowledge, and relevant IT assets (hardware, software, and networks). Meanwhile, incident in information security is a single or sequence of unwanted or unexpected incidents in information security that has a significant risk of disrupting the business process and threatening the security of information [28]. Managing IS security in SC ecosystem by using IoT technologies must be concentrated on wholly integrated

applications rather than stressing on in a single application. The main criterion that is important to emphasize SC managerial is the level of IS security, whereby the level of IS security among organizations is integrated by setting it at different levels. For instance, certain organizations have been set up as low level of safety, and other organizations have setup as high-level security based on their needs [19].

Table 3: Information System Security Management for IoT-enabled Smart City Challenges

Aspect	Challenges	IS Security	IoT Security
Governance	Formation and management of security standards / policies for IS	[6,14,24–27,29]	[14,45]
	Coordination of multiple stakeholders and organization	[24,28,58,61]	[14,39]
	Quality assurance	[6,62–64]	[56]
	Citizens' involvement	[14,50]	[39,54]
Integrity	Information security	[6,24,49]	[34,38,42,65]
	Information privacy	[6,15,16,24,49,63]	[34,37,45,65]
	Existing IS architecture	[14,61,66]	[7,39,65]
	Continuous cyber-attacks	[6,10,12,13,24,63,67]	[42,48,65]
Interoperability	Readiness of organization	[6,58,68]	[14,45]
	Interoperability implementation	[15,19]	[45,65]
	Secure communication	[4,6,62]	[38,48]
Personalization	Confidentiality	[4,17]	[37,56,65]
	Identity management	[17,69]	[17,35,38,42,48,54,56,70–72]
	Trust and system reputation	[4,14,73]	[42,45,57,68,70,74]
Self-Organizing	Threats/Risk management	[4,11,75]	[35,54,71,72]
	Lack of smarter security system	[24]	[71]
	Availability	[17,25,26]	[17,37,48,63,70,71,76]
	Reliability	[14,69]	[45,77]

Besides that, the SC characteristics, which will be enabled by IoT, are personalization and self-organizing. The personalization component is the individual provision of information, especially based on individual profiles and needs [81]. Self-organization, meanwhile, is a single concept of integrating the whole thing and can be defined as connecting anything to the internet, whether it is a computerized device system with no human-to-human or human-to-computer communication required [69]. One of the IoT elements is to gather and manage individual information automatically in real time. IoT typically consists of unlimited quantities of devices, individuals, and services that link and share information from various resources. Due to additional devices attached to each other in IoT ecosystems and the universal usage, the security and privacy issues come to be the key concerns.

The discussion on the challenges for each aspect is presented below:

4.1. Governance

The leadership and administration in the implementation of an SC can affect security issues. The SC must have all the means to maintain infrastructure and management issues, but weaknesses and frauds can result from inappropriate implementation. Therefore, it is important that the governance of IS security management within the SC is improved by taking into account the integration and exchange of information between different stakeholders, and by carrying out information security assessments. As it indirectly allows organizations to make effective and in-time decisions, the security level of the IS using IoT equipment must be maintained.

Information System (IS) security standard/policy development and management in governance need to be available and organized in the execution of collaboration and information sharing in the SC-enabled IoT [62,78]. Multiple IS incorporation by the use of different IoT devices enables the sharing of information in an SC. This condition will result in chances of IS security risks. The possible risks of cyber-attacks, such as distributed denial-of-service (DDoS), on public infrastructure will rise once devices are connected extensively to generate substantially huge volumes of information [79].

Besides that, coordinating between different stakeholders and organizations due to security management procedure in IS collaboration stays low [64,80]. There is an inadequate standard in the supervision of many stakeholders and no single standard is completely set in the governance of IS protection related to the acceptance, process management and dissemination of information through the use of IoT in SC [58]. In governance, the most comparable activities in IS integration in SC should be correctly described. The governance elements must include strategies, policies, processes and legislation, and accountability. The direction of an organization will be defined by strategies and policies, while processes and legislation will detail who, what, and how. Accountability explains the positions and responsibilities of stakeholders [62]. For example, in the health industry, it is important for medical personnel to safeguard patients' details. Otherwise, the data is open vulnerably, and worse, exploits the responsibility of the staffs for it, so they should be kept responsible for this to prevent future abuses [52,81].

Security measurement for the exchange of information, transmission, cooperation, decision-making, and execution of information exchange during the phase of IS integration at SC must be well-established for IS quality assurance [6,62]. Secure management would therefore require safe monitoring by the coordinator, where the function of the coordinator is to add and remove the IS involved in integration [52,81]. Quality assurance shall ensure that all decisions, processes, and activities remain in accordance with requirements to prevent service risks prior to their occurrence [82]. In order to ensure compliance with information security policies, standards and procedures, rules, regulations or contractual requirements of each company, the implementation of auditing and digital forensic processes is therefore critical [10].

Digital forensic is becoming more critical as an investigative activity for tracing and analyzing criminal and fraudulent activities. Digital forensic is all about cybercrimes, mobile forensics, investigating methods, and analyzing illegal incidents with aims to gather digital evidences. Information will be obtained for law enforcement purposes. Digital forensic may be aided by Intrusion Detection and Prevention Systems (IDPS), as it may confirm to be an important instrument, where its purpose is to conduct initial discovery, track malicious behaviors, and likely avoid further major harm to protected systems. An IDPS is therefore a very valuable instrument for the processing and interpretation of forensic evidence, which can be used for the purposes of a legal proceeding [31].

Other than that, involvement of citizens in SC ecosystem is needed to sustain the IoT usage. A low rate of citizen participation is due to lack of confidence and poor IoT knowledge levels. In order to address this problem, people need to recognize that IoT devices and related services can secure their personal information and help build a sense of empowerment [14,48]. Another important security and privacy measure is the understanding of cyber security and privacy. This is because some citizens do not understand this form of event and the negative impacts it can have, and are thus not in a condition to make decisions on the effect it can have on their privacy standards [83]. Cyber security awareness can begin at early levels, such as kindergartens and schools. Teachers or academic staffs can educate by teaching the implications and risks of cyber incidents. Teachers should also teach what is new, thereby ensuring a better image of the level of knowledge at personal and community levels [31]. Furthermore, it is also important to take social aspects into account. Thus, the "smartness" of a city relies heavily on the participation of citizens in SC projects via numerous communication channels comprising of online portals, social media platforms, and smartphones. In order to share experience and expertise, SC requires people to be actively linked in public locations, public transports, and at homes [4].

4.2. Integrity

Each part in SC, targeted and hacked in IS via cyber-attacks, would breach the integrity of information sharing and the privacy of information of users [82]. The definition of integrity is to ensure that unauthorized changes to system components are protected. Measurement to protect the content, authenticity, and continuity of the message must be taken [52]. There is no

unauthorized alteration of information by permitted or unauthorized personnel, and the information is internally and externally consistent [65, 84].

The weakness of IS security management in SC via the use of IoT will allow unauthorized users to retrieve information [58]. It can cause unauthorized data alterations, damage to information, and loss of information. Thus, the guarantee of information will be questioned by people including the impacts. As a consequence, the security of details that will affect the day-to-day activities of a company is not guaranteed [63, 73]. Information with credibility is reliable information that helps the organization in making the correct decision.

Other than that, the process of preserving data and information confidentiality, authenticating, identifying data, and controlling user access will be the subject of data protection. Theft of identities and phishing are some of the threats to information security, i.e., attempts to trace the misuse of one's financial information, duplication of user accounts, and fake sales or hacker promotions, which can result in data and information being disclosed, updated, and destroyed. Consequently, the integrity of information and data will decrease significantly, and users would lose confidence [65, 73]. Another example is, in medical applications, the node should be able to confirm that the data is sent from a proven trust center. Therefore, by changing the unknown key, the network node and coordinator for all data will make measurements to the Message Verification Code (MAC). Accurate MAC code measurement guarantees the network coordinator that a trustworthy node executes [85].

In addition to that, privacy concerns often affect the integrity of information. Privacy is the right to monitor and protect a single individual's private information. Security must guarantee that without the permission of the owner, none of the single bit of information obtained for a particular user can be shared with others. One of the most critical steps to protect privacy is the creation of rules/policies that have the capability to obtain confidential information in order to protect privacy [52]. Private information is collected in the IoT-enabled SC environment, where various devices are part of public services, for the users to decide with whom the information can be distributed [65,86]. Processing confidential information and the right of users to disclose information on the internet or social media on digital networks are the focal points of this privacy. SCs are exposed to privacy leaks and the collection of information by hackers, particularly, when private information is collected, distributed, and processed. Revealed privacy in SCs may include the identity of a user, venue, transportation movement, health status in healthcare, intelligent surveillance lifestyle, and home and community smart energy. It would be a big mistake to expose this privacy-sensitive data to untrusted or unauthorized people in the real world and cyberspace [73].

Compared to the SC setting that requires IS integrated architecture, some other elements of the constraints of the current IS architecture are linked to initial implementation in silos. The design is divided into software, hardware, and processes [64]. The software architecture is critical for delivering connectivity and allowing IoT devices to share resources between integrated organizations. The hardware/network architecture must be capable

in supporting the IoT-critically disseminated computing environment. In an organization, the use of IoT can impact existing business processes. Therefore, to help the innovation in computing and technology, there is a requirement to integrate IoT technology in organizational activities.

Furthermore, a big data project with massive amount of data will arrive in real time. The number, velocity, and variety of data can complicate the process of storage and analysis used to produce important information [48]. Increasing the amount of IoT devices used by SC in IS will provide hackers with opportunities for information security risks as many SC-related devices have low levels of security. IS security monitoring vulnerabilities present a threat to cyber-attacks exposing data to leakage [63, 65, 75] and access breaches. The lack of preparation to handle current cyber-attack threats would result in information being destroyed and lost. Cyber-attack is a security threat that is able to affect the expense of mitigating organizations [75]. Thus, system stability in terms of the system's ability is to react without getting worse because of unexpected attacks. The device must also be capable of protecting other network points from any attacks if one IoT computer is hacked. Therefore, mechanisms to ensure the protection, availability, accuracy, and integrity of the information system must be established during the sharing and processing of information in the SC ecosystem. One of them is the Intrusion Detection and Prevention System (IDPS) which is a computer or software program designed for network or system monitoring. It recognizes weaknesses, reports malicious attacks, and imposes protective methods to keep up with the progress of computer-related crimes via multiple response techniques [87].

4.3. Interoperability

Interoperability is a mechanism for sharing data and using knowledge that combines two or more systems or elements. Interoperability requirements make the system integration process vague, inadequate, and complicated, if not difficult, to execute [86, 88].

The vulnerabilities in IS protection make it impossible to be secure in the management of information exchanges, especially with a view to promote interoperability in the interaction and coordination processes of different IS that would allow services to citizens [24, 54]. Organizations' preparedness to use IoT in organizational activities is still poor and must be strengthened. An automated connection is required between various devices, facilities, and programs. The use of various technologies provided by IS providers would contribute to the need to separately manage the device. Security risks to information inside the SC would be indirectly revealed in the implementation of interoperability between organizations by using different levels of IS protection [80, 89].

Therefore, it is difficult to ensure that the interaction process between IoT devices is complete in each organization that includes multiple devices, especially with regard to memory, power, and time constraints [48]. So, before organizations are ready to be integrated, the requirements for the implementation of interoperability should take into account different levels of IS protection set by the company. This is to ensure that the integrated system's security is maintained [15, 19, 45].

Other than that, secure communication is another critical factor that must be highlighted during integration [65]. It will guarantee the security of authentication, confidentiality, and integrity of the linked data. It also prevents a message exchange from being repudiated, and preserves the identity of the users involved. Moreover, it is insufficient to protect IoT devices solely to ensure that the IoT system is completely protected [38,48].

4.4. Personalization

Personalization services are delivered according to individual profiles and preferences in a unique and precise way [79]. Confidentiality and privacy prevent data to go against unauthorized access where data indicates the security of an exposure to sensitive data that is deemed to be the critical issue. For example, in a medical context, sensitive and personal information about a patient's well-being is required and relied on to be transmitted, so the patient's data must be shielded from unauthorized access that may be harmful to the safety of the patient. Encryption will provide this sensitive data with greater security by using a mutual key to secure communication [52]. In order to make life safer and easier, the IS used every day will automatically collect personal information in real time, which means that IS can also monitor everyday life activities. If the IoT system control is lost or stolen, it will be a serious potential security concern [74]. In comparison, in the internet world, there is no chance for attackers to access the information if individuals do not supply the necessary details.

One aspect that needs to be highlighted in information protection is identity management. The access control restrictions for approved users are also not adequately implemented. Consequently, attackers may take advantage of these vulnerabilities to retrieve unauthorized features and/or information, such as accessing user accounts, watching confidential files, manipulating user information, and modifying access privileges [17,69]. Moreover, in the functions of applications, authentication and session management are still not properly implemented. Cyber-attacks affect IS authentication by enabling third parties to manipulate the original data to make it unreliable. Attackers can modify or manipulate other weaknesses via passwords, keys, and session tokens [17].

Besides that, trust and device credibility are essential aspects of using IoT to manage IS security. Trust ensures that information and resources are fully and confidentially accessed by users and IoT devices. Competent data collection, powerful data combination and mining, and enhanced user confidentiality are included in trust management. The present challenges are determining how trust is established between IoT devices, and determining the trustworthiness of a user in the use of IoT devices [17]. In IoT, consideration of two aspects of trust must be emphasized, consisting of trust concerning the interconnection among entities and trust in the system from the clients' viewpoint [57].

Personalization relies on the usage of private information, and in this IoT feature, protection and privacy issues are therefore major concerns. Organizations need to be fulfilled with security requirements, such as identity protection, privacy, data access control, precise authentication procedures, and trustworthy identity to resolve this.

4.5. Self-Organizing

Self-organizing is the administration of automated Machine-to-Machine (M2M) acceptance, processing, and distribution of information without human intervention [24,58,90]. In other words, in order to generate customer-oriented output that continuously operates to sustain itself, computers will function independently or coordinate with humans. The machines are thus autonomous entities that can gather and interpret information and provide guidance on the basis of research [90].

One aspect that needs to be highlighted in self-organizing is risk management. Risk is an essential aspect of the management of IS security in IoT-enabled SC. In the development and implementation of IS, risk is an unavoidable factor. Successful control of risk reduces an organization's operating risk. One of the key causes of IS failure is the weakness in risk management for IS growth, including prediction and evaluating risk [91,92]. IoT risk analysis requires the detection of assets, risks, and vulnerabilities. Failure to foresee and evaluate these vulnerabilities can lead to risks being generated. Other than that, the usage of poor application protection elements and the Application Programming Interface (API) can encourage a broad range of IS safety attacks [71,72]. In addition, the absence of a Smarter Security System to handle the identification of threats, the identification of anomalies, and the effects of predictive analysis affects IS performance [71]. Less secure and slower connections between IoT nodes lead to data leaks and other security breaches [74]. Another key element is availability and usability, which makes sure that the IS performs entirely at any time and every time an authenticated user is detected [17]. If any IS operation fails, the protection must ensure that equivalent resources are available, and as an added assurance, must allow M2M operations, i.e., real-time data collection will continue with IoT devices. Due to small and lightweight characteristics that make them operate on lower energy, the problems of resource constraint arises as most IoT devices have restricted handling and storage capacities [51]. Besides that, in medical practices, a network availability with effective admission to the patient's information is crucial, especially involving a system which contains important, sensitive, and potentially lifesaving information. Thus, the network must be available all the time [85].

The IoT technology enables users to be self-organized and personalized with data-driven decisions. Data-driven decision-making is a process that involves the collection of data based on established concrete objectives and the discovery of evidence, trends, associations, observations, and knowledge from this information. This expertise is then used to build or evaluate processes, operations, structures, policies, and techniques to support the data/system owner [5]. Information monitoring includes multi-device collaboration, which can effectively improve the accuracy and reliability of user-acquired information without fail. Another important problem is failure to collect the right data, as it can become a life-threatening matter for the citizens. Therefore, appropriate techniques can be used to ensure the IS is accurate, complete, reliable, and secure from malicious attacks during information transactions [52]. By using IoT technology, it allows information to be managed by machines, and enhances IS protection in the SC, such as protection against data leaks. By determining a corrective and preventive plan that

focuses on safety concern, each company in the SC needs to deliver a holistic risk management strategy.

5. Conclusion

This paper discusses the major challenges in the IS security management for IoT-enabled SCs. The document analysis discovers security challenges according to five aspects, namely: (i) governance, (ii) integrity, (iii) interoperability, (iv) personalization, and (v) self-organizing. It has been found that it is more complicated to protect IS from the heterogeneous IoT in SCs. At anytime, anywhere, and on any device, confidential data is exposed to malicious cyber-attacks. This study is expected to assist SC policy makers, city planners, and practitioners in understanding and addressing the challenges in sustaining IS security management for IoT-enabled SCs. This will lead to planning and the development of SCs to improve the citizens' quality of life. Future work must identify authentication features that are appropriate for IS security management by adopting IoT in SC environment. The aim is to overcome any unauthorized access to the sensitive and confidential information due to cyber-attacks.

Conflict of Interest

The authors declare no conflict of interest.

Digital Transformation

ABSTRACT

This paper is an extension of previous research that has been done on factors affecting digital payment adoption in the UAE. This study focuses on analyzing which relevant demographic factors affect new e-payment technologies, mainly in the smart city Dubai, with more complexities and dynamics of variables that affect users' behavior toward adopting new technologies. The current research included a wider range of demographic factors compared to previous studies. Quantitative methods were conducted using a survey of 270 individuals living and working in Dubai. This study revealed that e-payment adoption is very high, which could be aligned with the national digital transformation strategy of the UAE. The results of the chi-square test for independence indicate that using e-payment technologies is positively associated with the level of education and the level of income. This is confirmed by the fact that the UAE's demographic shape is identified by its high-income groups, positively influencing the residents' e-payment adoption. Surprisingly, the significant results for independence were not found between using e-payments and the gender, marital status, age group, and the current professional position in Dubai. This research's contribution adds to both academia and industry in the digital transformation and technology adoption field. Based on the results, it is recommended for decision-makers to leverage education, digital literacy, and income to accelerate moving toward a cashless economy. However, not having statistically significant differences between the rest demographic variables and adoption will encourage businesses and e-payment service providers to deliver new innovative e-payment models and technologies in a smart city context.

1. Introduction

The fourth industrial revolution (Industry 4.0), with its emerging technologies, brought new innovative technologies to reshape the whole economy and our life [1]. However, it is creating many concerns about security, privacy, and governance. It is crucial to adopt a socio-technical approach to manage digital transformation and conduct effective change management strategies to expand it from an enterprise to a society level, especially when it comes to smart cities as more complex systems in the digital economy.

The United Arab Emirates (UAE) case in incubating digital transformation using emerging technologies is considered one of the most exciting cases to be analyzed and investigated in the

Middle East. Especially after the launch of the national digital transformation agenda and several futuristic acceleration initiatives toward the digital economy. All of that had created an atmosphere to accept and adapt faster to technological disruptions, mainly in the fast-growing E-Commerce sector [2]. With growth expected to reach 23% annually between 2018 and 2022 with an estimated 27 billion dollars only for E-Commerce transactions in 2022 based on a study done in collaboration between Dubai Economy Department and Visa [3].

The UAE's strategic goal to shift from an oil-dependent economy to a knowledge-based one, firstly accelerated pace of digital transformation projects across all the government sectors, followed by digital innovation in several business sectors to renovate their models and realign with the digital faster. For instance, Emaar properties initiated noon.com, and Amazon

*Corresponding Author: Anas Najdawi, anas.najdawi@gmail.com

www.astesj.com

<https://dx.doi.org/10.25046/aj060214>

acquired souq.com as evidence of the enormous potential of digital business in this region [4]. Additional factors that enabled the UAE to grow at a higher rate regarding e-commerce and digital payment could be linked with the UAE consumer demographic profile. Such profile is featured by a young internet-savvy population, with high social media usage that reaches 99% and 91% for the internet penetration. Along with more than 66% for smartphone penetration and above 7 hours per day for time spent online, which all of this considered higher than the most mature e-commerce markets worldwide [3]. Moreover, the availability of efficient and reliable payment technologies is crucial to digital business growth in any country. The momentum of digital transformation in the payment services in the UAE attracted Big Tech companies such as Apple, Google, Alibaba, and Samsung to provide their digital payment services as well as local companies such as Etisalat, Beam, and local banks to compete in this sector [5].

The fourth industrial revolution we live in with a broad spectrum of emerging technologies is expected to play an indispensable role in reshaping the whole payment industry. For example, artificial intelligence technologies, particularly machine learning algorithms and face recognition, are currently used to conduct payments as a new trend in China [6]. Also, blockchain technology enabled the creation of cryptocurrencies as a way of payment used by several countries [7], [8]. The success of new E-payment services based on such emerging technologies depends on the maturity of such technologies, environment, and end-users acceptance, which are extremely dynamic and changing fastly, hence require a continuous re-evaluation of relevant demographic factors.

This paper is an extension of work initially presented in the IEEE International Conference on Digitization (ICD) [9], which recommended the need to adopt a socio-technical design approach for digital transformation and innovation the payment services in e-commerce which is evolving exponentially in this region. That initial work recommended the need to reinvestigate to which extent demographics variables are relevant and directly affect e-payment adoption in general and especially for the smart cities context in developing countries. The lack of studies in the current literature about emerging new e-payment technologies in developing countries' smart cities is apparent. We believe this area was not addressed in the existing literature according to our best knowledge or only tackled technical perspective without considering the social factors. Thus the current research aims to provide a more in-depth analysis of how demographic variables influence the adoption of existing and new e-payment technologies in Dubai as one of the most promising smart cities in the whole region.

The paper is organized as follows. A literature review on related work about e-payment adoption is introduced in section two, followed by section three for the used research methods. Results and discussions are covered in section four; last, the conclusion and the implications of these study findings to the industry and potential new directions for research are presented in section five.

2. Literature Review

Day by day, the diffusion of new e-payment technologies is expanding globally. The World Bank reported that small retailers

in 2015 received 15 trillion dollars via technological payment channels, representing 44% of global transactions [10]. The percentage of people who are using cash decreases substantially; for instance, cash users in North America dropped from 16% to 11% in 2020 compared to 2018. In emerging economies, the rate of cash usage is still comparatively higher [11].

It is noticeable that there is a growth in e-payment adoption in countries with active governmental digital transformation and ongoing smart city programs such as China, India, UAE, and Saudi Arabia. For instance, In 2019, both UAE and France headed other countries in delivering a complete set of Citizen to Government (C2G) e-payment services [12]. That reflected how the UAE government is serious about moving into a cashless economy, as revealed by the Central Bank of UAE in 2018 [13]. However, the same report reflected that the UAE ranked 27 among 72 analyzed countries regarding government e-payment adoption ranking. This indicates that more efforts are needed in this full digital transformation journey.

2.1. Demographic Variables and e-Payment Adoption

Even though many studies about e-payment adoption were found in the literature, few studies associated with the adoption of e-payment in the UAE were found, some analyzed the E-payment adoption principally through SWOT and TOWS matrix [14]. Others used the extended TAM model to analyze the factors affecting the adoption of e-payment systems through a survey of university students in the UAE. In [15], the author investigated the factors affecting the adoption of smart government services in the UAE compared to other Arab countries [16], [17].

Authors studied how people from different socio-economic classes would behave differently toward using e-payment technologies and found that people with higher-income use e-payment technologies more than lower-income people since last have less access to ICTs. [18] Additionally, authors found that the level of education and age affected the behavior of users toward e-payment systems obliquely; because the older people are, the more education they get, and the more income they receive, which is proof that it impacts the use of e-payment. However, the study revealed that there is no relationship between e-payment usage behavior and any commodities and services (i.e., food, bills, transportation, etc.)

Their work also studied the correlation between using e-payment and specific channels such as credit and debit cards for online transactions, E-Money, and Money transfer via internet banking channels. The results showed a positive relationship between Credit and Debit Cards usage on the internet and the behavior toward e-payment systems, And a negative relationship between the behavior toward e-payments and e-money. Regarding the relationship between user behavior and money transfer via internet banking is found to be partially supported.

Other studies studied the usage of digital wallets via analyzing the relationship between awareness about digital wallets and demographic variables such as age, gender, income, etc. According to the study, people in the age group of 36-45 are the most interested in learning and using e-wallets. While the people in the group age 26-36 are more interested in using e-wallets than using credit and/or debit cards due to its continent features. As for

the relationship between the awareness of using e-wallets and gender, males are more interested in using e-wallets than Females; additionally, males prefer using e-wallets over cash use [19].

Other authors surveyed Ghana to investigate the influence of demographics on user's behavior toward using e-payment systems and found no significant relationship between gender and the use of e-payment. However, there is a relationship between age and the behavior to use e-payment systems, more precisely, the satisfaction of using the systems; because young people have more expectations from e-payment services, they are not satisfied easily. The level of education is not significantly related to the behavior toward e-payment systems usage; however, according to the study, users with a higher level of education feel less secure using the e-payment services [20].

A different study Investigated how socio-demographic factors affect usage of e-payment systems in Malaysia. According to the study, older people are less motivated to use e-payments. Married people use e-payment more than unmarried people due to the fact that married people have higher living expenses; additionally, they use e-payment systems more frequently than unmarried people in order to save time. The level of education is a significant factor affecting the use of e-payment services; according to the researchers, people with high education levels tend to use more e-payment services compared to less educated people. Additionally, the income level was found to be an important factor to affect the use of e-payment services; people with lower income levels are unlikely to use e-payment services compared to people with a high level of income [21].

The primary demographic variables, such as gender, age, educational level, and income, were studied to explain their impact on e-payment adoption [22]. The different categories of the population were examined to demonstrate this, involving students, employees, professionals, and business people. The research was designed to estimate the individual opinion related to the e-payment systems and their frequency along with demographic aspects. As a result, the educational process has a direct impact on the adoption of new e-payment systems.

The impact of age and occupation on e-payment systems usage and their influence on anticipated benefits and speed was examined by [23]. The study revealed that the significance of age on e-payment usage was not that considerable compared to the occupation variable. Furthermore, the paper demonstrated the substantial difference in the perception of e-payment technologies among such categories as business, retired employees and employees, students and homemakers; the three last-mentioned categories have a clear awareness about benefits and speed. Besides, these people have different opinions about facilitating conditions.

A research determined that e-payment card acceptance is not significantly affected by such factors as age, gender, education, and marital status of respondents. However, none of the previous studies investigated how demographic variables could impact e-payment adoption in the context of smart cities with a higher level of digital transformation and maturity of e-government services such as UAE [24].

2.2. E-Payment Channels

Previous studies showed that quick, easygoing, and trustable-payment techniques played an essential role in the success and spread of e-commerce worldwide [25].

Examining e-payment adoption requires an understanding of the new emerging technologies evolving fast and disrupting the whole sector, creating both new opportunities and challenges such as face-recognition algorithms, Blockchain, and implantable/wearable devices that definitely will gain greater acceptance in the future [8], [26].

There are main e-payment channels identified in the previous studies summarized in Table 1 [25], [27], [28] which include but are not limited to the following.

Table 1: The Main e-Payment Channels Identified in Previous Studies

Payment Channels	Description	Examples
Cards payment	This channel includes cards issued by banks such as debit cards, credit cards, internet shopping cards, or issued by shops such as prepaid cards, gift cards, and loyalty cards that can be used in certain shops at the cashier. [29]. Most of these cards are using Radio frequency identification technology (RFID).	Bank cards, e-Dirham card, transportation Nol card for transportation, and emirates ID.
Web Wide Web (WWW) Payment	This method requires the use of the internet and websites to make a payment, mainly through internet banking websites or making online transfers or pay through a third party intermediary [30]	This includes PayPal or Cashu, as well as debit accounts using bank transfers.
Mobile Devices	This channel includes all smart mobiles of devices to conduct a payment mainly through several technologies such as digital wallets and mobile applications, SMS, and NFC. [31] [32]	Examples include mobile payment apps like Samsung Pay, Ali Pay, Apple Pay, bank applications, or payment through telecommunication providers such as Etisalat or DU.
Financial Services Kiosks	This approach includes conducting payment transactions through self-service digital kiosks or stand-alone-machines. [33]	Examples of this approach include both non-financial services such as paying bills or purchase a product or a service, as well as financial ones such as money transfer or payment using ATM.
Biometric payments	These approaches include using authentication based on biometric features of the body that are hard to copy and impersonate. [34]	Using several biometrics for an authentication mechanism, including faceprint, fingerprint, voice, and iris recognition
Cryptocurrency	This includes payment that is based on Blockchain technology as the main component of the IT infrastructure. [8]	Among the most well-known cryptocurrencies can be Bitcoin, Ethereum, etc.
Wearable devices	This approach of payment is still new amongst others and includes wearing devices or objects to substitute in the near future card and mobile payment. [26]	Real examples include payment through digital rings or smartwatches.

All previous studies reflected in general the significance of individuals' demographics on technology acceptance/adoption, such as e-payment technologies [35]. However, up to our best

knowledge, no sufficient studies have been made, including new emergent e-payment technologies with regards to demographic variables in smart cities as a special unite of analysis, where the adoption tends to be more complex, dynamic, and faster than other cities [36]. The primary objective of this study is to fill such gap and investigate the role of demographic factors in adopting several e-payment technologies in the case of Dubai as a case of smart city, having in mind the following main questions:

- To which extent various e-payment technologies are adopted in Dubai nowadays?
- How is the e-payment adoption affected by demographic variables?

3. Methods

3.1. Data Collection

The study was carried out using a self-administered online questionnaire, which consisted of two major sections. The first section comprises ten questions intended to collect demographic data and some information about using different e-payments technologies. The demographic information section included eight questions designed to collect information about the characteristics of the participants. Information was gathered about residents' income, current professional position, age, marital status, gender, and educational level. The second section contains 28 statements meant to examine those factors that influence the perception of using e-payment. The items in this section essentially required the respondents to choose to what extent they agreed with each statement. A Likert scale of one to five (1 = strongly disagree, 2 = disagree, 3 = agree to some extent, 4 = agree, and 5 = strongly agree) was used so that participants could rate their degree of agreement regarding the survey statements.

3.2. Sample and Population

The participants in this study were individuals living and working in Dubai. In this research, a nonprobability sample technique is used for collecting responses. To achieve the objectives of the current research, the researchers of this work used the convenience sampling technique, which is a type of non-probability sampling where population elements are selected for inclusion in the sample based on the ease of access. In some cases, judgment sampling is used where the researchers' judgment is used for selecting participants who are considered as representative of the population. A sample size of 270 eligible respondents was collected to conduct the study from the targeted population of individuals living and working in the Emirate of Dubai.

The pilot study was done on 15 individuals in Dubai before its dissemination to satisfy the face validity. Cronbach alpha, which is a measure of reliability based on the internal consistency of the constructs, was calculated and found to be 0.913. This indicating that the data collection instrument has attained a relatively high level of reliability. Hence, all items are retained.

3.3. Data processing and analysis

The respondents' collected data are recorded and coded in the Statistical Product and Service Solutions (SPSS v.25). For achieving the purpose of the study, a quantitative approach of

research is used. Additionally, we used percentages technologies for counting all the yes-category of the items listed in the research tool instrument to measure each factor that influences the perception of using e-payment methods. The researchers used a t-test to perform a comparative analysis of using e-payment technologies between the gender and marital status, where each one of them has two categories. They also used the ANOVA test to compare the different educational level categories, individual income, and age groups. To validate the stated hypotheses, the researchers used the Chi-Square test of independence to test the association between the demographic variables used in this study and the use of e-payment technologies.

3.4. Research Hypotheses

Since the researchers in this paper mainly aimed at investigating the influence of demographic variables such as income, current professional position, age, marital status, gender, and educational level on the adoption of e-payment technologies, this study attempts to test and verify the following six hypotheses.

H₁: There is a relationship between gender and adoption of e-payment

H₂: There is a relationship between profession and adoption of e-payment

H₃: There is a relationship between age and adoption of e-payment

H₄: There is a relationship between education and adoption of e-payment

H₅: There is a relationship between marital status and adoption of e-payment

H₆: There is a relationship between income and adoption of e-payment

4. Results and Findings

4.1. Demographic Characteristics of The Respondents

We conducted an online survey to analyze the adoption of e-payment technologies in Dubai based on different demographic variables. A total of 379 respondents visited the survey's link, and 270 respondents (71.2%) completed the survey.

Table 2 summarizes the demographic characteristics of the respondents to the survey. The table shows that 52.6 % of the participants were males, 10.4 % were born before 1980 (Generation X), 32.6% were born between 1980 and 1994 (Generation Y), and 57% were born in 1995 or above (Generation Z). Twenty percent of the participants were married, and in terms of education, 26.3 % of them had High School or lower, 12.6 Diploma, 41.5% Bachelor's degree, 11.5% Masters and 8.1% were Ph.D. holders. In terms of the monthly income, the study found that 55.2% of the respondents have an income below 10000 Dirhams. 14.3% from 10000 to less than 20000, 18.2% from 20000 to less than 30000, 5.9% from 30000 to less than 40000 and 6.3% having a monthly income of at least 40000 Dirhams

4.2. E-Payments Channels

The enormous development of e-payment technologies in Dubai led to an increase in adopting such technologies by its

residents. Table 3 shows that out of 270 respondents, 84.3% of the individuals in Dubai stated that they are now using e-payment technologies, only 8.6% never used it before, and 7.1% used it in the past they are not using it anymore. This indicated that the majority of individuals in Dubai having experience in e-payment technologies.

Table 2: Demographic Characteristics of the Sample

Criterion	Category	Number	Percent
Gender	Male	142	52.6
	Female	128	47.4
Age Group	Less than 1980	28	10.4
	1980-1994	88	32.6
	1995 and above	154	57
Marital Status	Single	215	79.6
	Married	55	20.4
Education	High school or lower	71	26.3
	College (2 years program)	34	12.6
	Bachelor's degree	112	41.5
	Masters	31	11.5
	Ph.D.	22	8.1
Monthly Income	Below 10000	149	55.2
	10000 up to less than 20000	38	14.1
	20000 up to less than 30000	47	17
	30000 up to less than 40000	18	6.7
	40000 or above	13	4.8
Total		270	100

Table 3: The Frequency Use of e-Payments

Category	N	Percent
I am now using e-payment	226	84.3
In the past, I used to deal with e-payment, but am not using it now	19	7.1
I have never used it before	23	8.6
Total	268	100.0

Despite the enormous development of payment technologies for the governmental sectors in Dubai, the individuals' acceptance rates for the different e-payment channels have been found to be satisfactory. According to the survey's results, about 76 percent of individuals gave preference to Contactless Cards. However, 24 percent of them prefer to use cash until now. Furthermore, the acceptance rate of Online Payment(s) was found to be 66 percent, while 46 percent of individuals relied on Mobile Payments. Wearable Payment Devices and Digital Currency are seen to have lesser excitement among individuals, where 5 percent of the respondents believe that they would be using each one of these techniques. The Website Domain Payments and ATM through Different Mobile Applications are also seen to have even lesser excitement among individuals where only one percent of the individuals in Dubai believe that they would be using each one of these techniques. Finally, the rate of acceptance of Artificial Intelligence Payments is only 0.6 percent. Even we expected that Artificial Intelligence Payments would not be used at all at the time of data collection of this research since that technology was not available but in a few smart cities around the world. As per the diversity of people in Dubai, we expect that those who used that

technology initially comes from these cities and will make these technologies transfer faster to Dubai based on government support to attract new technologies for their residents.

Out of the 51 nationalities that participated in this study's survey, the acceptance rates of different payment channels for the 11 dominant nationalities living in Dubai are summarized in Table 4. The table revealed that most of the dominant races selected Contactless Cards as their first choice with a percentage exceeding 80% for the Canadians, Indians, Pakistanis, Lebanese and Saudi Arabians, while it was between 68 and 77% for UAE, Egyptian, Iranian, Chinese and Jordanians. The Online Payments are selected as a first choice for the Syrian (85%) and Chinese (75%), and as a second choice for the Canadian (80%) and most of the dominant nationalities (50 to 69%), but not for the Lebanese, who selected Mobile Payments as a second choice. Only the Chinese have chosen Mobile Payments as their first choice, and all the other dominant nationalities set this digital mode of payments as their third choice with percentages of users around 50%.

Table 4: The Distribution of e-Payment Channels Based on the Dominant Nationalities in Dubai

	e-Payments Channels						
	Online Payment	Contactless Cards	Mobile Payment	Payment Kiosks	Wearable Payment Devices	Digital Currency	Artificial Intelligence payment
UAE	60% (53)	77% (53)	55% (53)	2.8% (53)	4% (53)	3.5% (53)	15% (53)
Jordan	64% (25)	68% (25)	56% (25)	25% (25)	0% (25)	4% (25)	8% (25)
Egypt	69% (13)	77% (13)	53% (13)	31% (13)	0% (13)	7% (13)	7% (13)
Syria	85% (13)	61% (13)	46% (13)	54% (13)	7% (13)	15% (13)	0 (13)
Lebanon	36% (11)	82% (11)	46% (11)	18% (11)	0% (11)	0% (11)	9% (11)
Saudi Arabia	66% (6)	100% (6)	17% (6)	16% (6)	0 (6)	0 (6)	0 (6)
Iran	62% (8)	75% (8)	50% (8)	25% (8)	0% (8)	0% (8)	0% (8)
Canada	80% (15)	87% (15)	40% (15)	7% (15)	6% (15)	0 (15)	0 (15)
India	62% (25)	80% (25)	38% (24)	13% (24)	8% (24)	8% (24)	4% (24)
China	75% (4)	75% (4)	100% (3)	75% (4)	50% (4)	50% (4)	25% (4)
Pakistan	50% (12)	91% (12)	42% (12)	25% (12)	8% (12)	0 (12)	0 (12)

4.3. The Use of e-Payment technologies for Regular Services

The participants in the survey were asked to identify the most frequent uses of e-payments for regular services, such as paying utility bills, food, clothing, electronics, phone internet, insurance, travel, education, road toll, and entertainment. The analysis of data revealed that most individuals in Dubai use e-payments for food (77%), clothing (71%), entertainment (67%), phone internet (57%), utility bills (48%), and travel for leisure (41%), whereas the paying for road roll, education, and electronics were used by about 35% of the individuals in Dubai for each one of these regular services.

For investigating the most frequently used e-payment techniques -based on location, the survey respondents were asked which e-payment techniques they use most regularly and from where. As observed in Table 5, more than 47% of Dubai individuals used Online Payments most frequently from home, 45.1% at shopping malls, 26.6% at work, 24.9% at the bank, and 19.2% at school. More than 48% of individuals are using Contactless Cards most frequently at home, 58.1% at shopping malls, and around 25% at each of the work, banks, and schools. The use of Mobile Payment and Payment Kiosks ranked third and fourth, were 33.3% and 17.4%, respectively, of the individuals in Dubai, are using these two e-payment techniques from home. Almost 35% and 20% of the individuals are using them at shopping malls. Mobile Payments are used by about 20% of the individuals in Dubai at either the bank or at work. However, Payment Kiosks for almost half of this number for the same regular services. Less than 5% of individuals are using Wearable Payment Devices, Digital Currency, or Artificial Intelligence Payment at any one of the mentioned regular services

Table 5: Percentages of the Most Frequently Used e-Payment Channels based on the location

e-Payment Channels							
	Online Payment	Contactless Cards	Mobile Payment	Payment Kiosks	Wearable payment devices	Digital Currency	Artificial Intelligence payment
Home	128/ 47.4	131/48.5	90/33.3	47/17.4	13/4.8	11/4.1	11/4.1
Malls	122/ 45.1	157/58.1	93/34.4	53/19.7	12/4.4	10/3.7	13/4.8
Work	72/26.6	69/25.5	56/20.7	33/12.2	11/ 4.1	5/1.8	5/1.8
Bank	67/24.9	70/25.9	55/20.3	28/10.3	8/2.9	8/2.9	7/2.6
School	52/19.2	66/24.4	31/11.4	22/8.1	6/2.2	5/1.8	4/1.5

4.4. Comparative analysis of using e-payment techniques between groups

This part of the research identified the difference in using e-payment technologies among the different categories of each demographic variable used in this study. The investigation is based on the differences in using e-payments values between the different categories of each variable by analyzing and examining the Mean scores (M) and Standard Deviation (SD) of each category's values supported by performing the two independent samples t-test and ANOVA test.

As predicted, findings of the study show that males are more interested in using e-payment technologies (M = 3.91, SD = 0.81834) than females (M = 3.72, SD = 0.90083). As shown in Table 6, results from an independent samples t-test indicated that the difference between the two genders was significant, $t(268) = 1.810$, $p = 0.071$ at a 10% alpha level.

Likewise, the married participants were outperformed (M = 4.0242, SD = 0.67237) the singles (M = 3.7690, SD = 0.89818) in using e-payment technologies. Moreover, the results from an independent samples t test showed that the difference between the

two groups of the marital status was significant, $t(108) = -2.332$, $p = 0.021$.

Table 6: Group mean scores in relation to the gender and marital status variables

Variable	Group	Mean (M)	Standard Deviation (SD)	t-cal.	p
Gender	Male	3.9108	0.81834	1.810	0.071*
	Female	3.7213	0.90083		
Marital Status	Single	3.7690	0.89818	-2.332	0.021
	Married	4.0242	0.67237		

*The mean difference is significant at 0.10 levels.

Table 7: Descriptive Statistics for the Using of e-payment for the Educational level, income, and the Age variables

	N	Mean	Standard Deviation	Std. Error	95% Confidence Interval for Mean	
					Lower Bound	Upper Bound
High school or lower	71	3.7793	.85994	.10206	3.5758	3.9829
College	34	3.8333	.71657	.12289	3.5833	4.0834
Bachelor's degree	112	3.7143	.91573	.08653	3.5428	3.8857
Masters	31	4.0323	.85355	.15330	3.7192	4.3453
Ph.D	22	4.1818	.71067	.15152	3.8667	4.4969
Below 10000	149	3.7987	.85847	.07033	3.6597	3.9376
10000 up to less than 20000	38	3.8333	.88955	.14430	3.5409	4.1257
20000 up to less than 30000	46	3.8986	.83109	.12254	3.6517	4.1454
30000 up to less than 40000	18	3.9074	.73924	.17424	3.5398	4.2750
40000 or above	13	3.9692	1.14167	.31664	3.0793	4.4591
Less than 1979	28	3.9881	.79857	.15092	3.6784	4.2977
1980-1994	88	3.7311	.99918	.10651	3.5194	3.9428
1995 and above	154	3.8420	.78493	.06325	3.7170	3.9670

Additionally, the ANOVA test's large p-values indicate no significant differences among the different categories of the participants' income, educational levels, and age groups regarding the use of e-payment technologies. Moreover, the descriptive statistics presented in Table 7 show that participants with high education levels tend to use more e-payment technologies compared to less educated participants increased slightly and gradually from 3.77 for the High school or lower educational levels to 4.18 for the Ph.D. holders. Even though the p-value of the ANOVA test was large for the monthly income, the study found that this variable is slightly affecting the use of the e-payment technologies; people with lower income levels are unlikely to use e-payment services compared to people with a high level of income. Similarly, the study of e-payment technologies found that the participants born before 1979 are the most interested in using e-payment technologies, with an average of almost 4. While the

participants born between 1980-1994 are least interested in using e-payments technologies with an average of 3.73, and the young participants born after 1995 are in the middle with an average of 3.84.

5. Testing Hypotheses and Discussion

This study uses a sample of 270 individuals living and working in Dubai on a self-administered online questionnaire to assess how e-payment adoption is affected by demographic variables. The study tested and verified five hypotheses that assumed the adoption of e-payment technologies is influenced by gender, current professional position, age, educational level, marital status, and income level.

5.1. Hypotheses Testing

This section discusses the association between the use of e-payments and demographic variables aiming to investigate the importance of individual's demographics on the adoption of e-payment technologies. Findings of the study show that about 55% of individuals the Ph.D. holders and 52% of the Masters' holders are using Mobile Payments comparing with about 42% for the individuals with the lower education. This yields that the higher educated individuals in Dubai tend to use more Mobile Payments than lower educated individuals. On the other hands, Dubai's individuals with low income (less than 10000 dirhams) and students are using Online Payments significantly with a lower amount (about 60%) comparing with those individuals with high income or from none students current professional position categories (more than 71%) with a maximum percentage of users from the executives' category which reached to more than 82% of them.

Table 8: Chi-Square Test for Independence, H₀: Using e-Payment (Variable 1) and Variable 2 are Independent

Variable 2	Chi-square	Asymp.Sig. (2 sided)
Gender	3.291	0.193
Education	14.923353	0.060653
Marital Status	3.715201	0.156047
Monthly Income	18.292553	0.019137
Age	5.528197	0.237262
Current Professional Position	8.653823	0.565242

Table 8 shows the chi-square (χ^2) test results for independence between the using e-payment technologies and each of the demographic variables investigated in this research. Statistically significant results at a 5% alpha level were found between the use of e-payments and the monthly income (Asymp.Sig. = 0.019137) and at a 10% alpha level between the use of e-payment technologies and the level of education of the individuals in Dubai (Asymp.Sig. = 0.060653). This indicates that the relatively high income of the individuals and the high levels of education increase the opportunities for using e-payment techniques. Therefore, the use of e-payments is positively associated with the level of education and the level of income; hence, the 4th and the 6th hypotheses are supported.

In contrast, statistically significant results for independence were not found (with a (Asymp.Sig. more than the 5% alpha level) between the using e-payments and the gender, marital status, age group, and the current professional position of the individuals in Dubai. Therefore, the association between the use of e-payment technologies and each one of these demographic variables (as stated in the 1st, 2nd, 3ed, and the 5th hypotheses) is not supported.

Results of the study show that the majority of individuals in Dubai having experience in e-payment technologies. Despite the enormous development of payment technologies for Dubai's governmental sectors, the individuals' acceptance rates for the different e-payment channels be satisfactory. The chi-square (χ^2) test results for independence indicate that the use of e-payments is positively associated with the level of education and the level of income and supports the 4th and the 6th hypotheses (see Table 8). This is confirmed by the fact that the UAE's demographic profile is identified by its high-income levels, which positively influence the consumers' e-payment technologies adoption.

Surprisingly, the significant results for independence were not found between the using e-payments technologies and the gender, marital status, age group, and the current professional position of the individuals in Dubai (see Table 9). Therefore, the association between the use of e-payments and each one of these demographic variables (as stated in H₁, H₂, H₃, and H₅ hypotheses) is not supported.

Table 9: Results of Tested Hypotheses

No.	Hypothesis	Finding
H ₁	There is a relationship between gender and the adoption of e-payment	Not supporting
H ₂	There is a relationship between profession and adoption of e-payment	Not supporting
H ₃	There is a relationship between age and adoption of e-payment	Not supporting
H ₄	There is a relationship between education and adoption of e-payment	Supporting
H ₅	There is a relationship between marital status and adoption of e-payment	Not supporting
H ₆	There is a relationship between income and adoption of e-payment	Supporting

5.2. Discussion

The high growth rate of the digital transformation of payment transactions in the UAE across several sectors, especially in the government, backed with the vision to move for a cashless economy, forced many users to try new e-payments technologies that are not well prepared for it. By the time that created more familiarity with and acceptance to try new innovative e-payment channels [37].

This study revealed a more updated analysis of the demographic variable of this dynamic market on the mode of use and channels. Most of the dominant nationalities selected Contactless Cards as their first choice. Online Payments are selected as a second choice for most of them. Most of the dominant nationalities selected Mobile Payments as a digital mode of payments as their third choice, with percentages of users more than 56%

The present study reveals the fact that most users had experience in e-payment technologies. The research's remarkable

results revealed that about 70% of the individuals use more than one e-payment technology frequently. The most significant two categories of e-payments sectors included the food (77.4%) and clothing (70.7%), while payments for government services were the most versatile where 48.1% of the individuals pay for Utilities (Electricity, Water, Gas), 57.4% pay for Phone/Internet, and 35.6% for transportation and road toll gates.

Regarding the popularity of the payment channels, both Contactless cards and online payments have been dominating by 75.9% and 65.6% of Dubai individuals, respectively. Followed by Mobile payment (including Mobile Bank Apps, Apple Pay, Ali Pay and Samsung Pay) and Payment Kiosks (such as kiosks in shopping malls, airports, Etisalat/DU, DEWA, and Dubai Police) ranked the third and the fourth with percentages of users reached to 46% and 25% of Dubai consumers (individuals) respectively.

Other new emerging e-payment channels were lower than expected in terms of diffusion, such the new and innovative payments through Virtual currency (including mobile games currencies, Linden Dollars of Second life, and Facebook coins) and Artificial Intelligence payment (such as Face Recognition payment), as well as wearable payment devices (such as apple watch, rings, etc.) are all considered to be futuristic e-payment techniques used in emerging markets. These new methods are still being utilized rarely in Dubai (about 5% for each method), and the majority of the people who are using these technologies are expats mainly from China. These technologies are expected to be more dominating due to the reliability of technology, convenience, and specialization based on the needs of younger generations (i.e., Generation Z).

The fact that the UAE's demographic profile is identified by its high-income levels influences individuals' e-payment technologies adoption positively. As per the results of this study, the individual's monthly income is mainly the most crucial demographic variable for the adoption decision of e-payments. Additionally, this study found statistically significant results between the adoption of e-payment and the level of education. Therefore, the adoption of e-payments is higher for more educated individuals than those who were less educated. While the study found that the other four investigated demographic variables (age, gender, marital status, and current professional position) had no statistical influence on the adoption of e-payment technologies.

6. Conclusion and Implications

6.1. Opportunities for Theoretical Contribution

The results of the study can be utilized by the industry of the digital transformation and technology adoption/innovation field in relooking or revamping their strategies for digital payment technologies.

E-governments should pay more attention to education and income as results prove that using e-payment technologies is positively associated with the level of education and the level of income. Also, the companies in this field should devise the policies and strategies to attract more people to smart cities like Dubai, regardless of their demographic category, as results prove that the significant results for independence were not found between using e-payments and the demographic variables

investigated in this research, i.e., the gender, marital status, age group, and the current professional position of the individuals in Dubai.

Unlike the other studies, the researchers' contribution of this work is creating a proposed theoretical model with an opportunity for gap filling the demographic variables compared with the other studies. This will shed light on the need to design and create compelling digital payment services based on the socio-technical approach rather than the technical one in smart cities regardless of their citizens' demographic categories.

6.2. Implications and Future Work

This section highlights the future research based on the current work results, especially on analyzing the key factors affecting the adoption of new technologies and services provided by new Fintech services, which is evolving fast and making many questions marks on the future of the traditional e-payment service providers in the region. The implications of this study will update change managers and digital transformation practitioners, and consultants to identify relevant correlations among e-payment technologies and demographic variables for this region. This will help all organizations looking to consider digital transformation for payment to benefit from the result to design competitive strategies based on the innovation of e-payment services, which is more customizable, user-centered, Omni-channels, smart, and powered with AI and business analytics.

The current study is not without limitations of selecting one city leading the region in digital transformation, such as Dubai. In the future, it can be interesting to analyze additional cities and do comparative analysis among them. Another issue can be the focus on user's requirements/demographic analysis can be limited base on the socio-technical theory, which can include in higher levels of additional analysis requirements collected from a group of users, community, or the whole society. As we can go one step simultaneously, these limitations give implications to the researchers to move further in the current area of research. (The implications of this research will help both researchers and digital transformation practitioners, mainly in the government and leading businesses, to design and develop more effective digital payment services for people in the smart cities [35], [36] based on the socio-technical approach rather than merely technical one.

There are many opportunities for further research using the current variables of the study and the questionnaire on a broader scope. Further research may include individuals from other emirates in the UAE to explore the inter-relations among the current demographic variables and the factors affecting the adoption of e-payments in the UAE.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

In the phosphate industry, sulfuric acid is a key compound in phosphoric acid and fertilizer production. Industrially, the sulfuric acid H_2SO_4 is made generally in a sequence of three main steps: burning liquid sulfur with air, catalytic oxidation of sulfur dioxide SO_2 to sulfur trioxide SO_3 , and formation of H_2SO_4 by the reaction of H_2O with the SO_3 . The catalytic conversion of the SO_2 into the SO_3 is considered as the crucial reaction that affects the gas emissions and the performance of the process. In this paper, an industrial SO_2 conversion unit of four catalytic beds reactors with vanadium pentoxide as a catalyst, and three heat exchangers were modeled. The model was based on heat transfer, energy and mass balance equations, and the kinetic reaction of the SO_2 catalytic conversion was proposed and calibrated using the experimental plant data. The simulation of the four catalytic beds was carried out in steady-state and dynamic mode using Unisim Design R451 simulator. The proposed model was tested and validated using the studied plant measurements, and the accuracy of the model has exceeded 97%. A graphical interface of the SO_2 conversion unit was integrated to make it suitable for industrial use and operator training. Finally, a digital twin (DT) of the studied conversion unit was developed based on an architecture integrating the plant, the virtual system, and the communication part in a Distributed Control System (DCS) context. The developed DT in this work makes it possible to simulate in real-time the SO_2 conversion unit, predict the process performance, and optimize the unit efficiency.

1. Introduction

In the era of digital transformation and digital factories, a new concept has been deployed known as digital twin (DT). It is considered an important component in achieving a smart and intelligent manufacturing plant. Digital twins' concept or the virtual representation of a physical product was introduced the first time in [1]. In [2], authors have defined the DT as a technology that refers to the method that can model and describe the performance of a physical entity. They add that DT is the tool that enables the interaction between the real physical system, and its twin in the cyber world. In manufacturing processes, DT can represent a reliable base that provides an accurate prediction of process parameters and performance, which can be used for different monitoring and optimization tasks [3, 4]. The implantation of a DT must include three important parts: the physical part, the digital part, and the physical-digital communication part that ensures the connection between the physical and the virtual product. Thus, physical product data are generated and collected from the physical part of the DT, and feed

its virtual model to provide real-time simulation and prediction in real conditions [5].

In recent years, different researchers have focused on DT development and implementation for industrial issues. In [6], authors have worked on the reengineering of aircraft structural life using DT concept. They used a DT that was developed by integrating several models in a virtual software to study the design variation under different operating conditions. The virtual software model includes the most important models in the aircraft structural life field, such as the computational fluid dynamic (CFD) model, the structural dynamic model, and the fatigue cracking model. In [7], authors have investigated the DT-based geometric optimization of the centrifugal impeller (CI) with free form blades for five-axis flank milling. To do so, several experiments and variations were performed to adjust the virtual model of the studied CI to its real physical part. The virtual model in their case was developed based on the geometric modeling, the aerodynamic parameters evaluation, and the machining optimization. In [8], a DT model was proposed for hollow glass production lines. The developed DT makes it possible to simulate the production line behavior with real process data and optimize the design of the

production line. Indeed, DT aims to capitalize on advances in modeling and simulation aspects, since all observations and results that will be generated by the DT are, in fact, predicted by the virtual model of the studied system.

In the literature, several studies have been carried out to develop models that can simulate sulfuric acid processes with high accuracy. The most used process in sulfuric acid manufacturing plants is the contact process [9]. This process is based on three important steps: liquid sulfur burning, sulfur dioxide SO_2 catalytic conversion, and sulfur trioxide SO_3 absorption. The SO_2 catalytic conversion stage is considered as the most critical step in the sulfuric acid contact process. Considering the importance of this step, numerous studies have been performed to describe and optimize the SO_2 conversion reactor based on process modeling and simulation aspects. In [10], authors have presented a dynamic model to simulate the SO_2 catalytic oxidation over the vanadium pentoxide V_2O_5 catalyst. The obtained model was validated using an experimental setup of a fixed bed reactor, and a new process design was proposed to ensure zero-mission. In [11], authors have presented a model to simulate the SO_2 catalytic converter using a pseudo homogeneous perfect plug flow model, and the model has been solved using the COMSOL Multiphysics software. In [12], authors have simulated the SO_2 oxidation reactor by a series of tanks, and simulation results were validated using measurement collected from the pilot and industrial reactors. Another interesting work has been published recently in The Canadian Journal of Chemical Engineering, in which the SO_2 converter model was developed based on mass and energy balance equations, and simulation results were validated using industrial measurement [13].

In addition to the SO_2 catalytic converter, and due to the exothermicity of the SO_2 conversion reactor, heat exchangers (HE) are indispensable in sulfuric acid industries. In SO_2 conversion units, HE devices are used to adjust the temperature of the gas leaving each catalytic bed of the converter, before feeding the next catalytic bed. The cooling step between the SO_2 converter beds is necessary to reach a high conversion rate [14]. Thus, the Shell and Tube Heat Exchanger (STHE) is the most used type of HE in this industrial process. In this context, many researchers have focused on STHE modeling and simulation to study and optimize the heat transfer performance within these devices. For example, in [15], authors have developed a dynamic one-dimensional model of multi-pass STHE, and model equations were solved using the finite volume method. In [16], flow and temperature fields modeling and simulation in a small HE were investigated using the CFD package of ANSYS Fluent 6.3. Also, they tested different turbulence models, knowing: Spalart-Allmaras model, two k- ϵ standard and realizable models. It was concluded that the k- ϵ realizable model was the best to simulate the studied HE, assuming a fine mesh and a first order discretization. Using Aspen-HYSYS V7.3 simulator, an optimization work of the air heating unit within the paddy drying process has been performed [17]. Simulation tasks of the studied HE were performed in Aspen HYSYS under many operating conditions, while the design task was carried out in Aspen Exchanger Design and Rating (EDR).

This paper represents an extension of the work that has been presented in the 5th International Conference on Renewable Energies for Developing Countries (REDEC), in which authors

have modeled and simulated a STHE with different approaches, using ANSYS-Fluent, COMSOL Multiphysics software, Unisim Design R451 simulator, and Matlab-Simulink [18]. All the presented models were validated using an experimental setup under a wide range of operating conditions. However, the model developed in Unisim Design simulator was selected as the best model to simulate the studied system. Besides, the model was used to simulate an industrial sulfuric acid cooling unit and has shown a good accuracy with the plant measurement.

In the present study, a dynamic model of an industrial sulfuric acid conversion unit was proposed and simulated using Unisim Design simulator. The simulated unit comprises a SO_2 conversion reactor with four catalytic beds and three HE. The kinetic parameters of the SO_2 catalytic conversion reaction were determined using experimental data. The simulation was performed in steady-state and dynamic mode, and simulation results were validated using experimental measurement from the studied SO_2 conversion unit. Additionally, a DT architecture of the studied system was proposed. The physical system of the DT was represented by the industrial plant unit, while the virtual part was represented by the developed SO_2 conversion unit model. The communication part of the DT was developed based on the Communication Object Model (COM), to ensure the connection between the real unit and its virtual representation in Unisim Design simulator. Also, a graphical interface was developed to make the developed DT useful for industrial use.

2. Sulfur dioxide conversion unit description

In the sulfuric acid double contact process, the sulfuric acid is produced in three principal steps: liquid sulfur combustion, SO_2 conversion, and SO_3 absorption.

Firstly, the wet air is dried in a drying tower using the circulating sulfuric acid, to absorb moisture contained in the air. Secondly, the liquid sulfur is burned in a sulfur burner with the dry air, to produce the SO_2 necessary for conversion step. The gas mixture feeds the conversion unit in which the SO_2 is converted into SO_3 , using the vanadium pentoxide catalytic V_2O_5 . Finally, the SO_3 produced by the SO_2 catalytic conversion is absorbed using the diluted circulating sulfuric acid. The three exothermic reactions governing the sulfuric acid double contact process are given as follows:

The sulfur dioxide conversion step is considered as the main stage of each sulfuric acid manufacturing plant, and its role is to ensure the conversion of the SO_2 generated by the liquid sulfur combustion into SO_3 . Each catalytic conversion unit comprises generally a reactor of several catalytic beds and heat exchangers that are used to regulate the inlet temperature of each catalytic bed. In this study, the SO_2 catalytic converter is a four catalytic beds reactor, with three heat exchangers as shown in Figure 1.

The typical configuration of the SO₂ converter consists of a vertical cylindrical adiabatic reactor. The dimensions of the equipment, as well as the height of each catalytic bed, are variable according to the conversion unit operating parameters. The packed catalytic beds of the converter are the main components SO₂ conversion reactor. Each one of the packed beds is supported by perforated metal grids that help in retaining the catalyst and allowing the gas to flow through. The gases flow from the top to the bottom of the beds. Ceramic rollers are placed on the catalyst to avoid any movement that may be caused by the gases flow, and to facilitate the exit of the gases after passing through the catalyst. The vanadium pentoxide V₂O₅ catalyst used in the SO₂ catalytic conversion reactor is highly porous and presents a specific surface in which the active phase is deposited. It is considered as the typical and highly catalyst used in the SO₂/SO₃ conversion step, with an operating temperature between 370 °C and 630 °C [19]. The conversion reaction in each catalytic bed is identical, but the amount of the catalyst required for the reaction changes according to the SO₃/SO₂ ratio in the feed. For example, in the first three catalytic beds, the amount of catalyst increases as the SO₃/SO₂ ratio increases.

The gas mixture feeds the first catalytic bed at a temperature of 400–440 °C. Since the catalytic conversion of SO₂ is an exothermic reaction, the temperature of the gas mixture increases as the amount of the generated SO₃ increases until reaching the equilibrium point. At the equilibrium point, the forward and the backward reaction rate are equal. To increase the forward reaction rate, the gas leaving the first catalytic bed is cooled to a lower temperature value using a superheater heat exchanger. After passing through the second catalytic bed, the mixture gas is cooled again before feeding the third catalytic bed. Cooling the gas before feeding each catalytic bed is a strategy that is used to further increase the SO₂ conversion rate. The gas leaving the third catalytic bed passes through an intermediate absorption, in which the SO₃ generated by the SO₂ catalytic conversion is absorbed by the circulating sulfuric acid. This strategy is used to reduces the

amount of the reaction products, which also increases the forward rate of the conversion reaction.

3. Dynamic model of the conversion unit

In this study, the Unisim Design R451 simulator was used to model and simulate the studied SO₂ conversion unit. To develop the virtual model of the studied flowsheet under the Unisim Design simulator, it is necessary to go through two environments. The first environment that must be configured is the basis environment of the simulator, in which the configuration starts by specifying the chemical components involved in the studied process. For the components that are not presented in the simulator components library, they can be defined as new hypo-component using their specific chemical properties, such as the molar weight and the critical temperature and pressure value. For the SO₂ conversion unit, all components required to perform this simulation are available in the simulator components library. Another specification that must be defined in the basis environment is the fluid-package, which represents the equation of state that will be used to calculate and predict the fluids' properties. Thus, the Peng-Robinson fluid-package was selected for the gaseous phase, and the Non-Random Two-Liquid model (NRTL) was selected for the liquid phase. Table (1) summarizes the chemical components and the fluid-packages used to perform this simulation.

Table 1: Unisim Design components list for the SO₂ conversion unit process simulation.

Component name	Component formula	Fluid-packages
Oxygen	O ₂	Peng-Robinson
Nitrogen	N ₂	
Sulfur dioxide	SO ₂	
Sulfur trioxide	SO ₃	
Water	H ₂ O	NRTL
Sulfuric acid	H ₂ SO ₄	

Finally, the chemical reactions involved in the process must be defined in the simulator using the stoichiometric coefficients of the

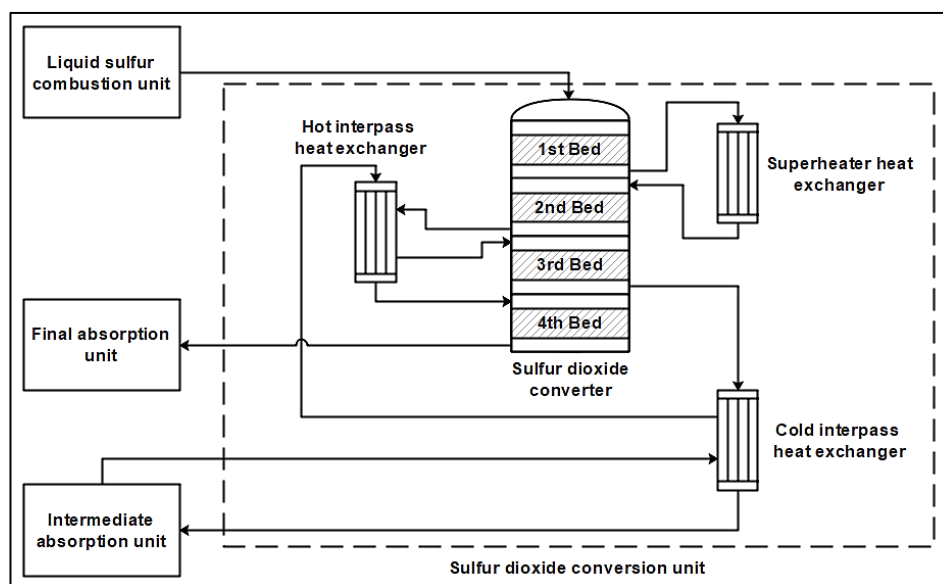

Figure 1: Sulfur dioxide conversion unit

reactants and the products. Note that the type of the defined chemical reaction must be also specified. In the Unisim Design simulator, five types of chemical reactions are provided: conversion reaction, equilibrium reaction, kinetic reaction, heterogeneous reaction, and simple rate reaction. For the SO₂ catalytic conversion reaction, the heterogenous reaction type was selected. Thus, the reaction rate of the SO₂ catalytic conversion is defined in the simulator as follows [14]:

$$r = \frac{K_1 \cdot P_{O_2} \cdot P_{SO_2} \cdot \left(1 - \frac{P_{SO_3}}{K_2 \cdot P_{O_2}^2 \cdot P_{SO_2}}\right)}{(1 + K_3 \cdot P_{SO_2} + K_4 \cdot P_{SO_3})^2} \quad (4)$$

where:

- r : kinetic conversion rate (kmole/m³.s);
- P_i : partial pressure of the component i (atm);

Constants K_1 , K_2 , K_3 and K_4 have been determined experimentally using industrial data to fit with the plant measurement, and are given as follows:

$$K_1 = \exp\left(15.31 - \frac{45501}{R.T}\right) \quad (5)$$

$$K_2 = \exp\left(-10.68 + \frac{93943}{R.T}\right) \quad (6)$$

$$K_3 = \exp\left(-9.95 + \frac{71655}{R.T}\right) \quad (7)$$

$$K_4 = \exp\left(-71.74 + \frac{437270}{R.T}\right) \quad (8)$$

Secondly, the simulation environment of the simulator must be configured by developing the flowsheet of the studied process, using material and energy streams, and equipment models. Table (2) shows the equipment models that have been used in the SO₂ conversion unit simulation:

Table 2: Unisim Design equipment models for the studied process simulation

Equipment model	Description
Plug flow reactors	Catalytic conversion
Shell and tube exchangers	Heat transfer

3.1. Catalytic converter model

The SO₂ converter was modeled with a series of reactors, in which each catalytic bed was modeled with a plug flow reactor (PFR). The PFR consists of a tubular reactor with a cylindrical pipe form, in which the transport mechanism is supposed ideal plug flow type. The following assumptions were considered in the model development: (1) the internal and external transfer resistances to mass and heat transfer are neglected, (2) the gas flow in the reactor is one-dimensional in the axial direction z , (3) the gas is radially isotropic, (4) the axial mixing in each PFR is supposed negligible. Under these assumptions, the proposed dynamic model of the SO₂ conversion reactor is given by the following mass and energy conservation equations:

Component i mass balance in the catalytic bed k :

$$\frac{\partial C_{i,gas}^k}{\partial t} = -\frac{4 \cdot \dot{Q}_{gas}^{k,in}}{\pi \cdot D_r^2} \cdot \frac{\partial C_{i,gas}^k}{\partial z} + v_i \cdot \rho_{bulk}^k \cdot r \quad (9)$$

Energy balance in the catalytic bed k :

$$\left[\epsilon^k \cdot \rho_{gas} \cdot C_{p,gas} + (1 - \epsilon^k) \cdot \rho_{cat} \cdot C_{p,cat}\right] \cdot \frac{\partial T_{gas}^k}{\partial t} = -\frac{4 \cdot \dot{Q}_{gas}^{k,in}}{\pi \cdot D_r^2} \cdot \rho_{gas} \cdot C_{p,gas} \cdot \frac{\partial T_{gas}^k}{\partial z} + (-\Delta_r H) \cdot v_i \cdot \rho_{bulk}^k \cdot r \quad (10)$$

Boundary and initial conditions:

$$z = 0, \quad C_{i,gas}^k(t) = C_{i,gas}^{k,in}(t), \quad T_{gas}^k(t) = T_{gas}^{k,in}(t) \quad (11)$$

$$z = H_r, \quad \frac{\partial C_{i,gas}(t)}{\partial z} = 0, \quad \frac{\partial T_{gas}(t)}{\partial z} = 0 \quad (12)$$

$$t = 0, \quad z > 0, \quad C_{i,gas}^k(z) = 0, \quad T_{gas}^k(z) = T_{bed}^k \quad (13)$$

where:

- $C_{i,G}^k$: molar concentration of the component i in the gas (mol/m³);
- v_i : stoichiometric coefficient of the component i in the conversion reaction;
- ρ_{bulk}^k : bulk density (kg/m³);
- r : reaction rate (kmole/kg cat.h);
- $C_{p,G}$: heat capacity of the gas (J/kg.K);
- $C_{p,cat}$: heat capacity of the catalyst (J/kg.K);
- ϵ^k : void fraction of the bed k ;
- T_G^k : temperature of the gas in the bed k (K);
- ρ_G : density of the gas (kg/m³);
- $\Delta_r H$: conversion reaction heat (J/mole).

In equation (9), the term on the left-hand side represents the component i mass accumulation in the gas. The first term on the right-hand side represents the component i mass contribution, and the second term represents the mass consumption of the components i . In equation (10), the term on the left-hand side represents the heat accumulation in the gas, the first term on the right-hand side represents the heat contribution, and the second term represents the heat generated by the catalytic reaction.

In the SO₂ catalytic conversion, the conversion rate is defined as the amount of SO₂ that has been converted into SO₃, and it is given by:

$$\tau_{SO_2}^k = \frac{\dot{Q}_{gas}^{k,in} \cdot C_{SO_2,gas}^{k,in} - \dot{Q}_{gas}^{k,out} \cdot C_{SO_2,gas}^{k,out}}{\dot{Q}_{gas}^{k,in} \cdot C_{SO_2,gas}^{k,in}} \quad (14)$$

At the equilibrium state, and using the reaction stoichiometry and the mass conservation, the molar concentration of the

components involved in the conversion reaction can be expressed according to the SO_2 conversion rate τ_{SO_2} as follows:

$$\dot{Q}_{\text{gas}}^{\text{k,out}} \cdot C_{\text{SO}_2,\text{gas}}^{\text{k,out}} = (1 - \tau_{\text{SO}_2}^{\text{k}}) \cdot \dot{Q}_{\text{gas}}^{\text{k,in}} \cdot C_{\text{SO}_2,\text{gas}}^{\text{k,in}} \quad (15)$$

$$\dot{Q}_{\text{gas}}^{\text{k,out}} \cdot C_{\text{O}_2,\text{gas}}^{\text{k,out}} = \dot{Q}_{\text{gas}}^{\text{k,in}} \cdot C_{\text{O}_2,\text{gas}}^{\text{k,in}} - \frac{1}{2} \cdot \tau_{\text{SO}_2}^{\text{k}} \cdot \dot{Q}_{\text{gas}}^{\text{k,in}} \cdot C_{\text{SO}_2,\text{gas}}^{\text{k,in}} \quad (16)$$

$$\dot{Q}_{\text{gas}}^{\text{k,out}} \cdot C_{\text{SO}_3,\text{gas}}^{\text{k,out}} = \dot{Q}_{\text{gas}}^{\text{k,in}} \cdot C_{\text{SO}_3,\text{gas}}^{\text{k,in}} + \tau_{\text{SO}_2}^{\text{k}} \cdot \dot{Q}_{\text{gas}}^{\text{k,in}} \cdot C_{\text{SO}_2,\text{gas}}^{\text{k,in}} \quad (17)$$

Assuming that the mixture gas is ideal, the SO_2 molar concentration $C_{\text{SO}_2,\text{gas}}^{\text{k}}$ can be given according to its molar fraction $X_{\text{SO}_2,\text{gas}}^{\text{k}}$ using the equation (18):

$$C_{\text{SO}_2,\text{gas}}^{\text{k}} = X_{\text{SO}_2,\text{gas}}^{\text{k}} \cdot \frac{R \cdot T_{\text{gas}}^{\text{k}}}{p_{\text{gas}}^{\text{k}}} \quad (18)$$

$$\sum_{i=1}^4 C_{i,\text{gas}}^{\text{k}} = \frac{p_{\text{gas}}^{\text{k}}}{R \cdot T_{\text{gas}}^{\text{k}}} \quad (19)$$

By summing the equations from (15) to (17) and using the equation (19), the gas flowrate $\dot{Q}_{\text{gas}}^{\text{k,out}}$ at the outlet of the catalytic bed k can be calculated by (20):

$$\dot{Q}_{\text{gas}}^{\text{k,out}} = \left(1 - \frac{R \cdot T_{\text{gas}}^{\text{k,in}}}{2 \cdot p_{\text{gas}}^{\text{k,in}}} \cdot \tau_{\text{SO}_2}^{\text{k}} \cdot C_{\text{SO}_2,\text{gas}}^{\text{k,in}} \right) \cdot \frac{p_{\text{gas}}^{\text{k,in}} \cdot T_{\text{gas}}^{\text{k,out}}}{T_{\text{gas}}^{\text{k,in}} \cdot p_{\text{gas}}^{\text{k,out}}} \cdot \dot{Q}_{\text{gas}}^{\text{k,in}} \quad (20)$$

3.2. Heat exchangers model

In this study, STHE used in the SO_2 conversion unit was modeled based on the heat balance between fluids in the shell and the tube side. In the STHE model development, the following assumptions were considered: (1) pressure drops are negligible, (2) fluids are single-phase, (3) fluids are incompressible, (4) fluids flows are one dimensional, (4) fluids flows are radially isotropic (5) radiations heat transfer are negligible, (5) heat capacities of fluids and solids are constant. Under these assumptions, the STHE model can be written in terms of energy balance equations in the tube side and the shell side [18]:

$$\rho_{\text{tb}} \cdot \dot{V}_{\text{tb}} \cdot C_{p,\text{tb}} \cdot \frac{dT_{\text{tb,out}}}{dt} = \rho_{\text{tb}} \cdot \dot{V}_{\text{tb}} \cdot C_{p,\text{tb}} \cdot (T_{\text{tb,in}} - T_{\text{tb,out}}) - \dot{Q}_{\text{ex}} \quad (21)$$

$$\rho_{\text{sh}} \cdot \dot{V}_{\text{sh}} \cdot C_{p,\text{sh}} \cdot \frac{dT_{\text{sh,out}}}{dt} = \rho_{\text{sh}} \cdot \dot{V}_{\text{sh}} \cdot C_{p,\text{sh}} \cdot (T_{\text{sh,in}} - T_{\text{sh,out}}) + \dot{Q}_{\text{ex}} - \dot{Q}_{\text{loss}} \quad (22)$$

where:

- $\rho_{\text{tb}}, \rho_{\text{sh}}$: densities of fluids in the tube side and the shell side, respectively (kg/m³);
- $\dot{Q}_{\text{tb}}, \dot{Q}_{\text{sh}}$: volume flow rate of fluids in the tube side and the shell side, respectively (m³/h);
- $C_{p,\text{tb}}, C_{p,\text{sh}}$: heat capacities of fluids in the tube side and the shell side, respectively (J/kg.K);

- $T_{\text{tb,in}}, T_{\text{tb,out}}$: inlet and outlet temperature of fluid in the tube side (K);
- $T_{\text{sh,in}}, T_{\text{sh,out}}$: inlet and outlet temperature of fluid in the shell side (K);
- $\dot{Q}_{\text{ex}}, \dot{Q}_{\text{loss}}$: heat transfer and heat loss in the heat exchanger, respectively (W).

The heat transfer between the tube side and the shell side, and the heat loss in the atmosphere are defined as bellow:

$$\dot{Q}_{\text{ex}} = U_{\text{ex}} \cdot A_{\text{ex}} \cdot (T_{\text{tb,out}} - T_{\text{sh,out}}) \quad (23)$$

$$\dot{Q}_{\text{loss}} = U_{\text{loss}} \cdot A_{\text{loss}} \cdot (T_{\text{sh,out}} - T_{\text{amb}}) \quad (24)$$

where:

- $U_{\text{ex}}, U_{\text{loss}}$: heat transfer coefficients (W/m².K);
- $A_{\text{ex}}, A_{\text{loss}}$: heat transfer areas (m²);
- T_{amb} : ambient temperature (K).

By substituting (23) and (24) in (21) and (22), the dynamic model of the STHE can be described by the following equation:

$$X' + AX = B \quad (25)$$

With:

$$A = \begin{bmatrix} 1 + \frac{U_{\text{ex}} \cdot A_{\text{ex}}}{\rho_{\text{tb}} \cdot \dot{Q}_{\text{tb}} \cdot C_{p,\text{tb}}} & -\frac{U_{\text{ex}} \cdot A_{\text{ex}}}{\rho_{\text{tb}} \cdot \dot{Q}_{\text{tb}} \cdot C_{p,\text{tb}}} \\ -\frac{U_{\text{ex}} \cdot A_{\text{ex}}}{\rho_{\text{sh}} \cdot \dot{Q}_{\text{sh}} \cdot C_{p,\text{sh}}} & 1 + \frac{U_{\text{ex}} \cdot A_{\text{ex}}}{\rho_{\text{sh}} \cdot \dot{Q}_{\text{sh}} \cdot C_{p,\text{sh}}} + \frac{U_{\text{loss}} \cdot A_{\text{loss}}}{\rho_{\text{sh}} \cdot \dot{Q}_{\text{sh}} \cdot C_{p,\text{sh}}} \end{bmatrix}$$

$$B = \begin{bmatrix} T_{\text{tb,in}} \\ T_{\text{sh,in}} + \frac{U_{\text{loss}} \cdot A_{\text{loss}}}{\rho_{\text{sh}} \cdot \dot{Q}_{\text{sh}} \cdot C_{p,\text{sh}}} \end{bmatrix}$$

$$X = \begin{bmatrix} T_{\text{tb,out}} \\ T_{\text{sh,out}} \end{bmatrix}$$

The overall heat transfer coefficients can be calculated using the exchanger sizes and material properties:

$$\frac{1}{U_{\text{ex}} \cdot A_{\text{ex}}} = \frac{1}{h_{\text{tb}} \cdot A_{\text{tb,i}}} + \frac{\ln\left(\frac{r_{\text{tb,o}}}{r_{\text{tb,i}}}\right)}{2\pi \cdot L_{\text{tb}} \cdot (r_{\text{tb,o}} - r_{\text{tb,i}}) \cdot \lambda_{\text{tb}}} + \frac{1}{h_{\text{sh}} \cdot A_{\text{tb,o}}} \quad (26)$$

$$\frac{1}{U_{\text{loss}} \cdot A_{\text{loss}}} = \frac{1}{h_{\text{sh}} \cdot A_{\text{sh,i}}} + \frac{\ln\left(\frac{r_{\text{sh,o}}}{r_{\text{sh,i}}}\right)}{2\pi \cdot L_{\text{sh}} \cdot (r_{\text{sh,o}} - r_{\text{sh,i}}) \cdot \lambda_{\text{sh}}} + \frac{1}{h_{\text{amb}} \cdot A_{\text{sh,o}}} \quad (27)$$

where:

- $h_{\text{tb}}, h_{\text{sh}}$: heat transfer coefficient of fluids in the tube side and the shell side, respectively (W/m².K);
- h_{amb} : heat transfer coefficient of the air (W/m².K);
- $r_{\text{tb,i}}, r_{\text{tb,o}}$: inner and outer radius of the tube (W/m².K);
- $r_{\text{sh,i}}, r_{\text{sh,o}}$: inner and outer radius of the shell (W/m².K);

- L_{sh}, L_{sh} : length of the shell and the tube, respectively (m);
- $A_{tb,i}, A_{tb,o}$: tube side inner and outer areas (m²);
- $A_{sh,i}, A_{sh,o}$: shell side inner and outer areas (m²).

Heat transfer coefficients in fluids circulating in the tube and shell can be estimated using the Prandtl (Pr), Reynolds (Re), and Nusselt (Nu) numbers:

$$\text{Pr} = \frac{\mu \cdot C_p}{\lambda} \quad (28)$$

$$\text{Re} = \frac{\rho \cdot U \cdot D_h}{\mu} \quad (29)$$

$$\text{Nu} = \frac{h \cdot D_h}{\lambda} = f(\text{Re}, \text{Pr}) \quad (30)$$

where:

- μ : fluid dynamic viscosity (kg/m.s);
- C_p : specific heat (J/kg.K);
- λ : fluid thermal conductivity (W/m².K);
- ρ : fluid density (kg/m³);
- U : fluid velocity (m/s);
- D_h : characteristic diameter (m).
- h : convective heat transfer coefficient (W/m².K);
- f : function of Re and Pr.

Several correlations can be used to relate these three dimensionless numbers, depending to the geometry and the flow type, knowing the free convection at vertical wall or the horizontal

plates, and the forced convection on flat plate. Thus, numerous equations are available to calculate the Nu number according to Re and Pr numbers, such as Dittus-Boelter equation [20], Sieder-Tate equation [21] and Gnielinski equation [22].

4. Model Simulation

The conversion unit simulation of the studied sulfuric acid plant was performed under the Unisim Design R451 simulator, using PFR and STHE models. The chemical components and reactions involved in the SO_2 conversion unit, and the appropriate fluid-packages were defined in the basis environment. Firstly, the simulation was configured and performed in steady state around an operating point before running the simulation in dynamic mode. Key stream properties of the gas mixture feeding the first catalytic bed are summarized in Table (3). For the PID controllers used to adjust the inlet temperature of each catalytic bed, the setpoint in the three first catalytic beds was configured at 440 °C, while it was set to 390 °C in the last catalytic bed. Equipment sizes and material properties were also introduced in the simulator to simulate the dynamic response of the unit. The flowsheet simulation of the studied SO_2 conversion unit under the Unisim Design R451 simulator is shown in Figure 2. Note that all the simulations performed in this study were carried out in a Dell Precision 5820 desktop, using 32 Go of RAM and Intel® Xeon® W-2123 CPU @ 3.60 GH processor.

Table 3: Gas mixture properties of the stream ‘G1’ feeding the first bed

Stream name	G1
Temperature (°C)	440
Pressure (kPa)	150
Flowrate Q(m ³ /h)	572.6
% N ₂ (molar fraction)	79.16
% O ₂ (molar fraction)	9.7
% SO ₂ (molar fraction)	10.87
% SO ₃ (molar fraction)	0.27

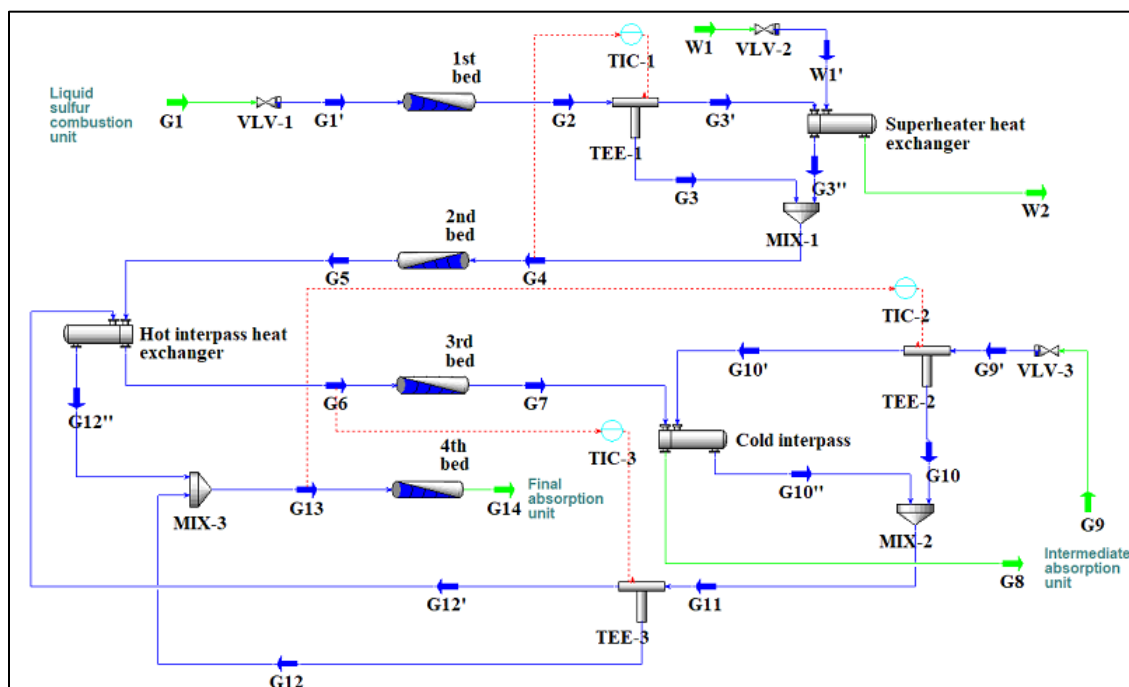

Figure 2: SO₂ conversion unit model simulation under Unisim Design

According to the steady-state simulation results, the gas mixture leaves the first catalytic bed at a temperature of 634.7 °C, since the catalytic conversion of SO₂ into SO₃ is a heat generating reaction. The conversion rate at the first catalytic bed was calculated by the model and found at the value of 63.43 %. As mentioned in the conversion unit description, the gas mixture is cooled before feeding the next catalytic bed to increase the SO₂ conversion rate. The outlet temperature value of the second and the third catalytic bed was 522 °C and 460.5 °C, and the conversion rate has reached 89.99 % and 96.59 %, respectively. At the outlet of the third catalytic bed, the gas mixture is sent to the intermediate absorption unit, in which the SO₃ produced in the first three catalytic beds is absorbed by the circulating sulfuric acid. The intermediate absorption step represents another way to well increase the SO₂ conversion rate. The absorption rate of the SO₃ in the intermediate absorption unit is about 99.98 %. The gas mixture feeds the last catalytic bed at the temperature of 390 °C and the remained SO₂ is converted into SO₃ before feeding the last absorption unit. The outlet temperature of the fourth catalytic bed was about 403.8 °C, and the cumulative conversion rate of SO₂ has reached the value of 99.97 %. Note that the gas transport along the four packed catalytic beds is accompanied by a pressure drop, and it is calculated using the Ergun equation. Table (4) summarizes the steady state simulation results of the SO₂ catalytic conversion reactor.

Table 4: Steady state simulation results of the SO₂ catalytic converter.

Reactor beds	1 st bed	2 nd bed	3 rd bed	4 th bed
Inlet temperature (°C)	440	440	440	390
Outlet temperature (°C)	634.7	522	460.5	403.8
Pressure drop (kPa)	1.707	1.735	2.084	1.662
Cumulative conversion rate (%)	63.43	89.99	96.59	99.97

Figure 3: First catalytic bed inlet temperature variations for the dynamic simulation

To simulate the dynamic response of the studied system, slight variations were applied on the first catalytic inlet temperature as shown in Figure 3. In this study, only the dynamic response of one catalytic bed was considered since the model is the same and remains applicable for all the other catalytic beds. Afterward, the SO₂ conversion rate and the outlet temperature of the first catalytic bed have been calculated and observed using the dynamic simulation of the studied unit. Simulation results of the first

catalytic bed dynamic response are presented in Figure 4 and Figure 5. Firstly, the inlet temperature of the first catalytic bed has been set to the value of 445 °C. As shown in the dynamic simulation results, the outlet temperature increased from 634.7 °C to 637 °C after a rise time 28.5 hours, and with a time constant of 10 hours. Then, a new steady state has been established at this point. When it comes to the SO₂ conversion rate, it decreased to the value of 62.68 %. After decreasing the inlet temperature of the gas mixture at the first catalytic bed from 445 °C to 430 °C, the system has evolved towards a new steady state point. The transit response of the system after this variation can be also described approximately with a time constant of 9.75 hours and a rise time of 29 hours. After that, the outlet temperature decreased from 637 °C to the value of 629.5 °C, while the SO₂ conversion rate increased from 62.68 % to the value of 64.91 %.

Figure 5: First catalytic bed SO₂ conversion dynamic response

5. Digital Twin architecture development and simulation

There are different understandings of Digital Twins. In some papers, the focus is on simulation [23, 24]. Others argue that DT integrates three dimensions: physical, virtual, and communication parts [25, 26]. In this paper, based on the three-dimension model, the proposed architecture involves three main components: the physical system, the virtual system, and the communication protocol. The physical system represents the real sulfuric acid

process. The virtual system is the developed and simulated model. For communication, the Open Platform Communications Unified Architecture (OPC UA), an industrial communication protocol that enables interoperability and connectivity of devices with different protocols [27], is used. In [28], a literature review discussing digital twins, it was mentioned that one of the main gaps in digital twins is the integration with the control system.

In the proposed architecture, the DT is integrated into a DCS context. The DT is installed on a server in the engineering room of the process distributed control system (DCS) (Figure 6). A copy of the graphical interface of the DT is also integrated into the control room for operators' daily uses. Using the OPC UA, an OPC server is developed to read real time data from field control stations (FCS) (Figure 7), which are connected to the real process. Then an OPC client is used to read data from the server and feed it to the core simulator developed using Unisim Design R451. A friendly user interface, inspired by the supervisory interfaces, is then integrated to show the results in both the engineering room and the control room. The communication between the modules of the DT, the OPC client, the core simulator, and the graphical interface is ensured based on the COM protocol. To communicate with the FCSs, the DT unit uses the appropriate DCS interface card. Regarding the Human Interface Station DT (HIS-DT), the communication with the DT uses the Distributed COM (DCOM) protocol.

The proposed DT of the studied SO₂ conversion unit was implemented and tested in a period of 24 hours. Measurements of the liquid sulfur and the air supply properties (flowrate, temperature, and pressure) were collected online with a sampling time of 1 min. Thus, the simulation of the studied unit was performed in real-time using the generated data and the actual

operating parameters of the plan as inputs. In Figure. 8 is shown the temporal variation of the four beds outlet temperature obtained by the DT simulation and the plant measurements. To compare and validate the simulation results, some statistical measures were calculated based on data illustrated in Figure. 8, knowing the determination coefficient R², the maximum error ME, the mean absolute error MAE, and the root mean square error RMSE. Table (5) regroups the results of the statistical comparison between the simulation results and the measurement values. Referring to Table (5), it is shown that results obtained by the simulation are in good agreement with the plant data with 97 %, which validates the model employed in the development of the SO₂ conversion unit DT.

Table 5: Statistical measures of the simulation results and plant data.

Measure	1 st bed	2 nd bed	3 rd bed	4 th bed
R-squared	0.9708	0.9838	0.9842	0.9787
Maximum error (°C)	11.14	6.32	8.52	6.20
Mean absolute error (°C)	7.76	3.97	6.20	5.16
Root mean square error (°C)	2.07	2.40	1.89	1.25

6. Conclusion

In this work, a digital twin framework of an industrial SO₂ conversion unit of four catalytic beds reactors was developed. The proposed digital twin integrates the plant, the virtual system, and the communication part. In the virtual system, Unisim Design R451 simulator was used to model and simulate the studied SO₂ conversion unit. For a smooth industrial integration, a graphical interface, inspired by the operator's graphical displays, was used. The graphical interface makes it possible to visualize the most important parameters obtained by the unit simulation, knowing the outlet temperature, the conversion rate and the pressure drop within the four catalytic bed. Regarding the communication part,

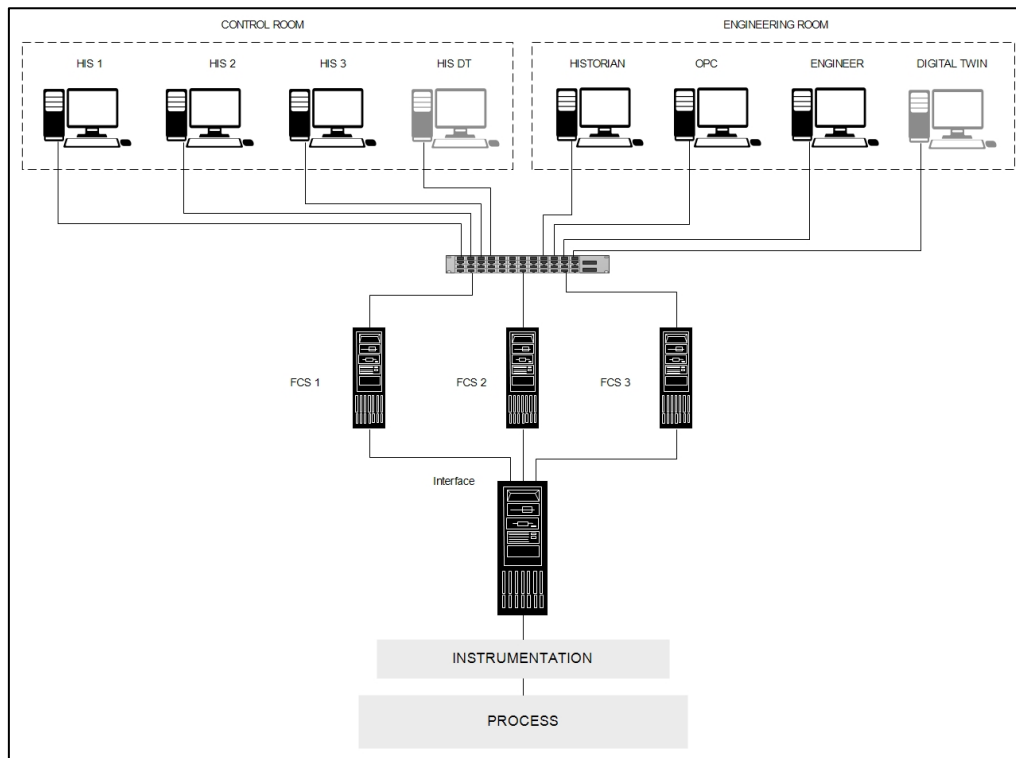

Figure 6: Digital Twin integration with DCS

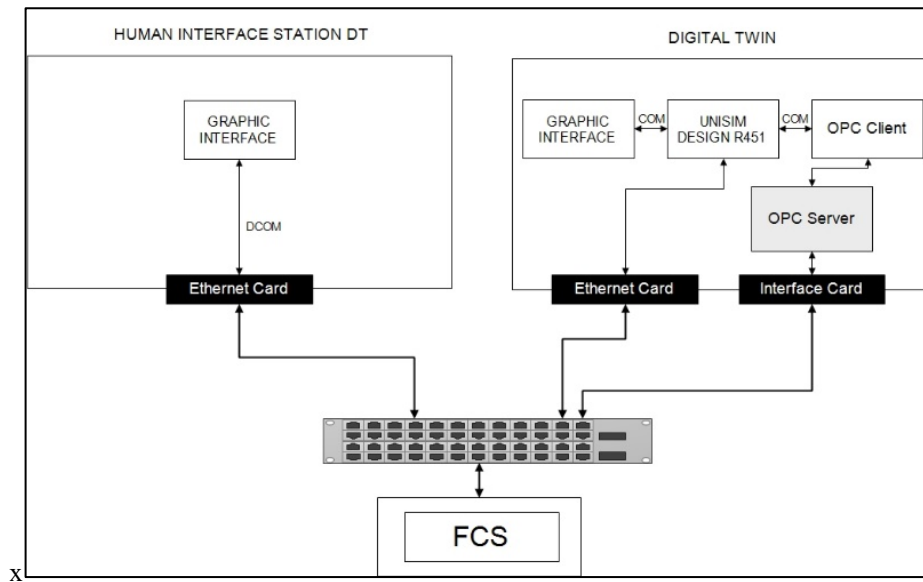

Figure 7: Digital Twin proposed architecture

Figure 8: Real-time simulation results of the proposed SO₂ conversion unit model

an OPC server is developed to read process real time data. Then an OPC client is used to feed it to the core simulator. The simulation model was tested and validated using data from the studied sulfuric acid plant, and the comparison has shown an accuracy that exceeds 97%. The digital twin will then be used to improve operations and simulate production scenarios for real time optimization and decisions.

In future works, the proposed approach will be combined with suitable control strategies for performance improvement of the studied industrial sulfuric acid plant.

ABSTRACT

The main purpose of this paper is to present a reusability approach that helps the designer to assess the best practice to restore a heritage building. Based on the literature review, the reusability process and attributes was used as a method to restore the heritage building. Considering these approaches helps the designer to achieve useful results in terms of the built environment and building performance; moreover, it helps the designer to identify the suitable new usage of the building. Also, the designer validated the building performance through using the TAS to assess the thermal comfort of the building after using passive techniques and design restorations. The obvious finding was the successful achievement through considering this approach and decreasing the interior temperature two degrees. This study can be assessed as one of the optimistic practices that considered the sustainability dimensions during the restoration process, as well as improving the thermal comfort of the building for the end user. The research paper provides a useful understanding of designers, restorers and researchers.

1. Introduction

This section is concerned with reviewing and describing the reusability process and its attributes. One of the conservation practice methods that has been used to preserve heritage buildings is to adaptively reuse buildings. Several researchers have stated that reusability in heritage buildings is part and parcel of restoring them. It is considered one of the solutions to revive abandoned or neglected houses, especially in old or historical neighborhoods. In addition, this method can help the designer to document the building. For this reason, understanding reusability and its attributes is an essential demand. It is stated that the change of a historical building's function and renewing it can lead to reuse by the public, as well as making it more sustainable [1]. This type of building has a mixture of cultural and historical values. It is said that there are several heritage buildings worldwide that cannot be used for the same purpose that they were built for [2]. This paper will study reusability and attributes as an approach, on the one hand. After that, the researcher will apply the results of studying this concept to one of the historical buildings in Taif in order to reuse it. That will be by determining the most prominent functional, structural and aesthetic changes, as well as taking into account the environmental, economic and social considerations of the building. In addition to that, the researcher will assess the

impact of applying the reusability approach in terms of thermal comfort.

2. View of the Heritage Housing Buildings in Makkah

Despite the multiplicity of tourist attractions enjoyed by the Kingdom of Saudi Arabia, archaeological and heritage sites occupy the most prominent place. Due to the kingdom's historical heritage, there are archaeological and heritage sites in different regions of the kingdom, representing a living record of successive civilisations in the Arab region. One of the most prominent regions in Saudi Arabia is Western Region, because it is one of the richest areas for heritage places. Sharbatly House, located in Jeddah at the entrance of Haret Al-Sham on the northern side, is a good example. It consists of four floors built with excavated stone in the year 1350 AH [3]. This shows the consideration of the environment through selecting local material. There are several heritage buildings, such as Nassif house. It is located in the heart of Jeddah city and it consists of four floors, with beautiful façades adorned with doors, windows and wooden pedals. These worked in a coordinated manner and were decorated with various decorations. This house was built in 1289 AH and was completed in 1298 AH, and was built with excavated stone castings in a square shape that was cut from the coast of the Red Sea. It is classified as a high architectural landmark and a witness of the architectural thought of the old style in Jeddah [3]. This house is distinguished by using Red Sea stone,

*Corresponding Author: Ali Alzaed, Dralzaed@gmail.com

which is a local material, and is also unique because of the material of the doors and windows, which has a clear impact in terms of the built environment. Another building, Noor Waly house, is located in the old city of Jeddah, and was built in the year 1280 AH. The Islamic Museum is a landmark place located in Makkah, and is a museum specialising in Islamic monuments and Meccan heritage [3]. Its style gives the impression of the prestige of this place. The decoration of this palace was selected to be ecological. Jeddah Municipality Museum is located in Al-Balad district, Jeddah. It has been restored and furnished with many heritage collections that were from people of Jeddah until recently, as well as artefacts dating back to before the Islamic era and pieces from the Islamic era [3]. There is a wide variety of pieces for this place. The Meccan Heritage Museum is located on the ground floor of Tariq Sindi's house. It contains various types of utensils; wooden, metal, and marble tools; Meccan textiles; guns, swords, and daggers, all of which are related to weapons; a number of artefacts, inscriptions, postage stamps, records, and notebooks [3]. Based on the reviews, some of these buildings have changed to become museums or some other use. This gives us a hint about the changeability of the function, which can lead to another successful story.

Alkateb House was later known as Al-Niyabah Palace. This house is located in the Al-Salam neighbourhood in Taif, and it consists of three floors built by Hamad Abdul Wahid, the private writer of the sheriff Aoun Al-Rafeeq in 1315 AH. It became deserted in 1388 AH. This building was marked by Roman artistic and architectural influences. It consists of a main foyer, at the end of which are staircase steps with marble stone handrails leading to the upper floors, and at the back, a large irregular orchard [3] and [4]. This building is distinguished by its view and styles, which include several local materials. This link with the local environment is considered as one of the successful opportunities for reuse for a different future activity, such as a café or hotel. Alkaaki House is located in the Al-Salamah neighborhood in Taif, in front of the defence building, and it consists of three floors. It was designed in the Roman style and built in 1358 AH. This house is distinguished by its various decorations and ceilings, and there is a garden in the rear belonging to it. There is also a section for men for women, known as the Harmalik and Selimk [4]. There are many experiences that have been applied to reusing heritage buildings in historical cities. The historical city of Erbil is an example, where the author mentioned the importance of having balance between conservation and reuse of these kinds of building [5]. The location of the selected case study and its design concept shows the possibility of adaptive reuse in the future as a commercial activity. This will be verified by applying the methodologies as described in the next section.

3. Methodology

The research paper uses several methods, as follows:

- Reviewing the heritage building background in the Western Region of KSA, and the reusability approach and its attributes.
- Developing and adopting reusability as a process and as attributes for green restoration of traditional buildings in Taif City, in keeping with its traditional character. This demands documenting the building using several methods such as AutoCAD, Survey and Photo Snap to assess the current situation.

- Assessing the impact of using a reusability approach on thermal comfort through using one of the most powerful energy building tools (TAS EDSL) [6].

4. Reusability Process and Attributes

Reusability as a process has been developed by several researchers. One of them developed a proposed iterative process model [7]. The process of this model for reuse-oriented software is reusability. This model consists of five stages as follows: Stage (1) Planning Phase: to study the expected profits in terms of technical aspects, reducing the cost of management and development [7]. Stage (2) Risk Analysis: this stage has two approaches which are reactive and proactive [7]. Each one of them has several features. Proactive features are the domain stable which means it is easy to invest directly for reuse and easy to predict the product features. However, reactive features mean it can be developed based on what is required. This approach is how to reengineer and adjust the current assets. Stage (3) Core Asset Development and Evolution: this includes determination and definition of features while understanding the similarities and differences between them. Furthermore, extension of the architecture if there is a clear demand and addressing the conflicts between the quality and product functionality. Stage (4) Change Requirement and Adaptation: a new requirement that will lead to changing the technology and environment. This usually will be during development work which is not expected. For this reason, the software has to be adapted to that and capable of managing it. Stage (5) Customer Evaluation: observation of the feedback of the customer [7]. To apply these terminologies and approach, there is a clear demand to understand what the main attributes of the reusability concept are, to be the basis for more understanding of this philosophy. This will give the research a clear vision about the possibility of its application on restoration of buildings. The main attributes are illustrated in Table 1:

Table 1: Reusability Attributes

Attribute	Description	References
Flexibility	Easily modify a system or component for new uses, different from what it was originally designed for.	[8] and [9]
Maintainability	Easy-maintenance software system or component to add capabilities or change or correct faults.	[9]
Portability	No external support is required to perform the functions, and has the ability to use alternative solutions at any time.	[8] and [9]
Variability	The ability of a component to be configured which helps to decrease understandability.	[8]
Understandability	Can also be defined as the level of understanding of the system's way of working.	[9]

Size	The lines of code and length of the software.	[8] and [9]
Complexity	The difficulty in understanding the design and implementation of software, which means reusing complex software.	[9]
Scope coverage	The number of features that the component provides through a particular feature.	[8]
Availability	How easy it is to retrieve a software component.	[10]

5. Reusability Process and Attributes for Green Heritage Building

In this research, selecting reusability as process and attributes may help designers to study and evaluate the feasibility of any building reuse. The current status of a green heritage building will be evident in the following case of a heritage building in the historic center of Taif. However, the process that has been adopted is shown in Figure 1.

Figure 1: Reusability process

5.1. In terms of planning stage

In this stage the building was abandoned. For this reason, to assess the benefit of restoring this building, the designer has to understand its main previous function and its retirement. In addition, it has to minimize the cost of development as well as its future management. As a result, there was a clear demand to document this heritage building as a study case for this research. For this reason, the building has been visited and surveyed to discover its boundary and investigate the environmental conditions as shown in Table 2.

Table 2: Survey points

Points	E	N
1	40.4081340	21.2749090
2	40.4080430	21.2748770
3	40.4080660	21.2748220
4	40.4081550	21.2748530

In addition, it is important to understand the previous function of the building, which was residential. For this reason, there is a clear demand to know the building components, elements and features. This was done through a manual documentation device which was used to draw building floors using AutoCAD software. All building floors were accessed by natural ventilation and daylighting, except one zone in the ground floor, as shown in Figure2.

5.2. Risk Analysis Stage

Rethinking the new use of the building was done through meeting with the building investors. They were confused about the optimal use that would bring them economic returns because housing investment was not encouraging for them, compared to similar experiences in the same location. It was considered that there were no museums in the city center, which could be an ideal option. However, one of the main landmarks of Taif City is Shubra Palace Museum, not far from their location. For this reason, the decision was to make the museum with a special and distinctive style. This is in terms of identification of the proposed activity, on the one hand. On the other hand, in terms of the building it has to be identified if it is proactive or reactive. In terms of being proactive, the building is stable and reliable and only needs a low budget. At the same time, the building can be reactive as there is a demand for some adjustment and reconfiguration in the ground floor, as shown in Figure2 and Figure3.

Figure 2 : Building floors.

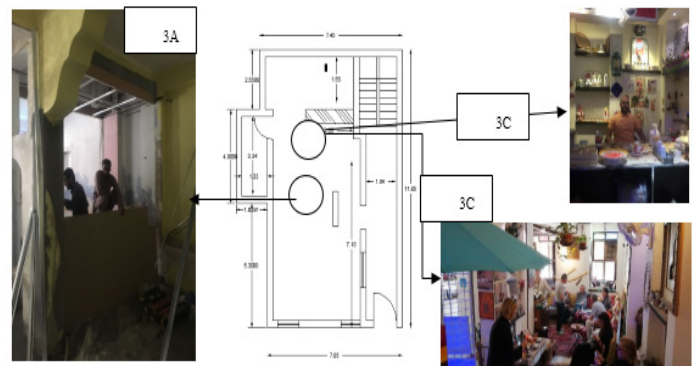

Figure 3: Ground floor before and after restoration

5.3. Core asset development and evolution

The decision was to make the museum with a special and distinctive style. This is in terms of identification of the proposed activity, on the one hand. In addition to that, the building has several attributes that support the decision. In the first place, the building style is heritage. This is obvious on the building facade which includes roshanah, which is the window made from wood. In terms of the interior, the building is capable of being a museum, as there were cavities on the wall as well as shelves. Most of the attributes considered during restoration are mentioned with more explanation, as indicated in Table 3. In addition to that, the ground floor zones have been mixed to be one zone as shown in Figure3.

The natural ventilation and daylighting did not reach the back section, which means it was not suitable for the future user.

Figure 4: Second floor restoration

5.4. Change requirement and adaptation

This happened during the building use and activation. Some of the zones have had their functions changed to be galleries, following which signs and paths on the floors were created to assist visitors. In addition, the ground floor has adapted a café to enhance activity for the museum which provides a service to visitors. The roof use has been changed to become a painting studio. All of these additions were after the building was set up with its new activity as a museum.

5.5. Customer evaluation

The overall impression of the visitors was very positive. This was evident by their enjoyment of the experience. In addition to the diversity found in the building is a café for hospitality, an art gallery, a drawing studio and a museum. All these factors enhance the visitor experience. A limitation that helps measure user satisfaction is the thermal comfort of buildings. Therefore the interior temperature of the building was evaluated before and after the restoration using the simulation software (TAS) as mentioned in the research methodology. The results of that will be explained in the following sections, and the building material and location description is shown in Table 4.

Table 3: Reusability green heritage attributes

Attributes	Descriptions
Flexibility	The designer removed the wall in the ground floor to have a large space and to let the air and light access the whole area, as highlighted in Figure 2 and illustrated in Figure 3. In addition, the skylight is adopted as the main hole as shown in Figure 4 (4E-4F), as well as the main wall being used for shelves as illustrated in Figure 4 (4C) and the staircase used as a store.

Maintainability	External electrical installations as shown in Figure 4 (4A). Plant pots easy to install, remove and maintain.
Portability	Fans and industrial lighting as shown in Figure 2 (2A).
Variability	The designer created the paths for the gallery as a guide, as in Figure 4 (4A). Indicative maps and configuration of the building were based on user needs, such as modifying the gallery to be a hospitality salon as shown in Figs. 4C and 4D, and using the heritage window (oriel window) to be bookshelves as shown in Figure 2B.
Understandability	Features of the rooms, ways of furnishing them and the building map in the distribution of its elements.
Size	Removing the wall of the ground floor and adding shade shelters as shown in Figure 2A. Some decorations on building façades may also fulfill an ecological function [11]. Agricultural ponds, wooden pergolas, shelves and gypsum decorations as shown in Figure 4G.
Complexity	Narrow space and lack of ventilation and lighting for some spaces; floors on the ground floor have more than one level; the electricity network was irregular and random; and the bathrooms were not suitable.
Scope coverage	<ul style="list-style-type: none"> • Outside coverage; turn it into an attraction. • Choose the right function. • Configure building activity from house to museum. • Enhance the returns through the configuration based on a coffee place, as shown in Figure 3C, and gallery (Figure 4A). Rent the rooms as hospitality places and ticketed areas, and configure the main roof as a painting studio.
Availability	All restorations and additions, such as removable wall, skylight as illustrated (4E and 4F), and shelters on the main door and windows as shown in 2A, are easy to remove and restore the building to its previous use.

6. Numerical Simulation

Distinctive physical models are utilized to depict the structure warm conduct contingent upon their particular needs, counting space warming, ventilation, cooling frameworks, inhabitants' practices, and budgetary viewpoints. The physical structure execution depends on the unraveling of the warmth move

differential conditions, which can be written regarding the energy preservation law:

$$Q_{\text{int}} + Q_{\text{source}} = Q_{\text{out}} + Q_{\text{stock}}$$

Where Q_{int} is the heat flux entering the system, Q_{source} the heat flux of an eventual heat source, Q_{out} the heat flux leaving the system and Q_{stock} the heat flux stored. The principal in and outcoming fluxes taking place in the heat transfer are the conduction through walls, the convection (both sensible and latent heat), the radiation and the ventilation.

Countless mathematical virtual products are these days accessible to take care of such physical issues, both in fixed and dynamic conditions. The consistent state approach is ordinarily used to survey the structure energy execution and prompts long haul examinations of various situations thank to their quick computations. In any case, a significant constraint happens since the dormancy of the structure envelope is totally disregarded. Consequently, dynamic warm models ought to be favored while breaking down energy sparing arrangements.

Building demonstrating and reproduction programming TAS was utilized to foresee energy execution, improve warm and subsequently inhabitant comfort (EDSL TAS 2017). The documents used to finish the model on TAS are the arrangement seen appeared in Figure 2. At first, the model made on TAS was an imitation of the current condition of the building. Hence, the underlying produced energy model was the reference point for enhancements.

In the present study, the following modelling assumptions are adopted:

1. It was expected that the residence is involved from 6pm-8am during non-weekend days and for an entire 24 hours during the end of the week.
2. The programmed recreation of characteristic ventilation (due to windows, entryways, ventilators, and different gaps comparative with their elevation and direction) will be thought to be the reasonable portrayal of the real wind stream (EDSL TAS 2017).
3. The National Calculation Method (NCM) information base will be utilized to apply to all zones (EDSL TAS 2017).
4. The development of the TAS model is dependent on compositional drawings (Figure2). In any case, to improve the model the impact of the encompassing trees was not considered in this reproduction. At first, utilizing the accessible design drawings of the genuine structure, the floor plans were attracted the 3D-TAS. The following stage in the model improvement was to characterize zones inside each floor for warm reproduction purposes. This zone definition was critical as it impact the manner in which the model would be dissected. The indoor warm exhibition of the building, especially identified with more elevated level warm definition, was essentially estimated and investigated by contrasting the hourly normal indoor air temperature and mean brilliant temperature of zones.

These days, there are two principle ways to deal with gauge human warm solace Predicted Mean Vote (PMV) furthermore, the

Percentage of Dissatisfied (PPD). These methodologies which consider a few ecological viewpoints, for example, dry bulb temperature, moistness, air speed and mean brilliant temperature (Figure 5) just as human factors, for example, warm obstruction and metabolic rate. Warm balance is inferred when the interior warmth creation in the body is equivalent to the warmth misfortune to the encompassing climate [12].

In the present study, the thermal conductivity (Watt/m².K) is assumed to be constant for any given material, and is independent of temperature; i.e.

$$\lambda = \frac{q}{A(T_1 - T_2)}$$

The U-value for a certain structure is expressed as the ratio of the density of heat flow rate through the structure q , W/m², and the difference between the internal and external temperature values, as follows:

$$U = \frac{q}{(T_i - T_e)}$$

It will be accepted that the Location properties of the designed building are the real current states of the building (Table 4).

7. Results and Discussion

With respect to the impact of the reusability approach on the built environment, the main changes that have been made are to reconfigure the ground floor to be one zone, as well as to install a skylight to be a wind catcher. These simple treatments were used due to the moderate climate of Taif. In contrast to hot, dry climates that require some different treatments. An example is the evaporative cooling that was tested on an apartment building in Baghdad [14]. All these measures can lead to enhancing the thermal comfort of the building. Before the reconfiguration of the building design and through the summer season, the outdoor air temperature was 35.6 degrees at 2.00 pm and the indoor air temperature for hall one was 34.54 degrees, almost one degree different, while hall 2 was 42.87 degrees at the same time, as shown in Figure6. However, after the reconfiguration, the ground floor became one zone. The indoor air temperature becomes 33.33 degrees, which means that it decreased by approximately one degree, as shown in Figure7. This gives a clear indication of the impact of the reusability approach through mixing the zones on improving the thermal comfort for the end user. In addition, the wind catcher can add value to that and enhance the thermal comfort

performance. During the wintertime, the outdoor temperature was 13.8 degrees and the indoor air temperature for hall 1 and hall 2 were 14.3 and 20.29 degrees, respectively. However, after reconfiguration of the ground floor, the indoor air temperature become 14.04 degrees, which is still higher than the outdoor temperature, as illustrated in Figure8.

The discussion above illustrates that the reusability building approach and reconfiguration can have a clear impact on the interior thermal comfort. In addition, the restorations of the design and application of some techniques such as a wind catcher can lead to improving the interior energy without any mechanical demands. Using these approaches and passive techniques is more beneficial than a huge restorations of the building, especially in heritage buildings.

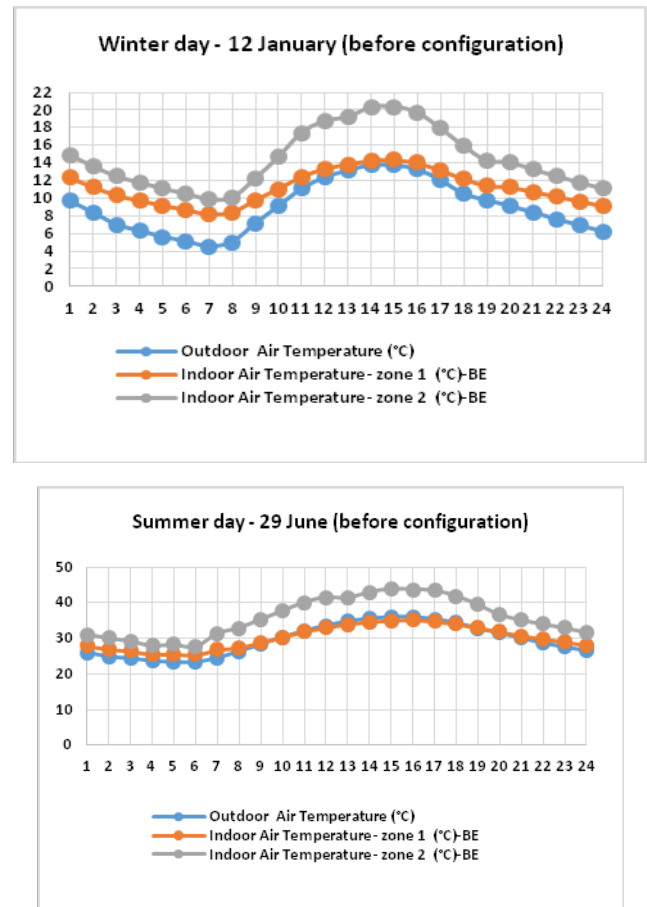

Figure 6: The result of outdoor and indoor temperature before configuration

Figure 7: The result of outdoor and indoor temperature after configuration

Figure 8: The result of outdoor and indoor temperature before and after configuration

8. Conclusions

The work of this research investigated the impact of using the reusability approach on the building restoration, usage and performance. This was clear in a hot and cold climate in Taif City. Usage of local material, a wind catcher, and reconfiguration of the interior design were investigated. One of the obvious results is the effect whereby the reusability approach can lead to a decrease in the interior temperature by two degrees in hot climates. In addition, using the reusability approach with some passive techniques is

more beneficial than a huge design reconfiguration. The numerical simulation results indicated that due to the restoration process adopted, there is a decrease in the inside temperature of the building. However, the small value of temperature reduction can be referred to the nice weather of Taif city, where the heritage building found. The most important conclusion is such restoration can lead to temperature reduction. Any way, we think that such restoration process might be important in hot weather cities.

ABSTRACT

Human have the god gifted ability to focus on the essential part of a visual scenery irrespective of its background. This important area is called the salient region of an image. Computationally achieving this natural human quality is an attractive goal of today's scientific world. Saliency detection is the technique of finding the salient region of a digital image. The color contrast between the foreground and background present in an image is usually used to extract this region. Seam Map is computed from the cumulative sum of energy values of an image. The proposed method uses seam importance map along with the weighted average of various color channels of Lab color space namely boundary aware color map to extract the saliency map. These two maps are combined and further optimized to get the final saliency output using the optimization technique proposed in a previous study. Some intermediate combinations which are closer to the proposed optimized version but differ in the optimization technique are also presented in this paper. Several standard benchmark datasets including the famous MSRA 10k dataset are used to evaluate performance of the suggested procedure. Precision-recall curve and F-beta values found from the experiments on those datasets and comparison with other state of the art techniques prove the superiority of the proposed method.

1 Introduction

Computer vision techniques are usually complex and time consuming, since every pixel of the input image needs to be processed through them. Saliency detection is the technique of finding the salient or important region in an image. So, researches in this field have become popular to reduce this type of computational complexities and shrink the search space of an input image in various vision related applications including object detection, action recognition, image segmentation, video surveillance, medical data processing, robotics and many more. Color contrast present between the salient region and the background is the most popular cue for saliency detection. Another prior that produces good result is the boundary prior which assumes that the boundary regions are mostly backgrounds. These are two popular and successful cues in saliency detection solutions. But, those cues are challenged when the salient regions have less color dissimilarities with the background, they are closer to the border or touch the boundary regions. In those complex conditions, relying only on contrast and boundary priors may not produce good results. So, a different method which does not exclusively rely on contrast based dissimilarities is presented in this study. Experimental results with popular standard datasets and comparison with other state of the art techniques proves the

superiority of the proposed system. Evaluation is done based on PR curves and F-Beta measures using publicly available state of the art benchmark results of different studies.

2 Related Works

Since there is usually a visible contrast between the salient region and its background, many researchers mostly relied on contrast prior. Moreover, boundary prior offered promising results in most of the cases.

Early saliency based researches emphasized on center prior which assumes that the salient regions are usually at the center of an image. Those methods usually biased the center of the image with higher saliency values. It was not always true and there are many examples where the saliency is not at the center of an image. So, it was a fragile assumption and nowadays researchers are not much interested in that cue.

On the other hand, boundary prior is an opposite assumption to center prior. Unlike its counterpart, it works better for objects which are not strictly at the center of an image. Although this assumption has some drawbacks, it resulted in better detection in many researches. This prior does not consider the condition where an

*Corresponding Author: Aminul Islam, CSE Discipline, Khulna University, Khulna-9208, Bangladesh, Contact No: +880 1911013641 & Email: aminul@ku.ac.bd

object contains some of the boundary parts. In [1] the shortest-path distance from an image region to its boundary is used as a cue for saliency detection. It shows that the boundary pixels can easily be connected to the image background instead of the foreground. As a result, it results in incorrect detection if an object is touching the boundary region.

In [2], the authors have taken into consideration the problems of boundary prior and introduced weighted boundary connectivity to successfully solve them and presented a better boundary prior based implementation. They also have proposed a robust optimization technique to combine multiple saliency cues to achieve cleaner saliency maps.

In [3], the authors have used contrast based spatial features along with boundary prior to generate their state of the art saliency detection result. They measured region based color dissimilarity of a superpixelized image found by applying the SLIC algorithm on an input image and suppressed the background using boundary prior as a cue to it. They also have combined the contrast based salient region with boundary based output and fine-tuned the combined saliency map using Gestalt thresholding technique to generate the final salient region.

In [4], the authors have presented a color map based saliency detection technique. It is the weighted average of various color channels. They combined it with border map to acquire the final saliency output. This color map is used successfully in [5] to calculate salient region in an image.

Seam is an optimal 8-connected path of pixels in an image. It is introduced by Avidan et al. in [6] for content aware image re-sizing and suggested for image enhancement too. Yijun et al. has used seam information in their saliency detection technique [7] with success.

Many methods including [8]–[12] have combined multiple saliency maps to produce better optimized versions successfully. Some of them became complex and their implementation and performance in real world situations are still to be tested. In [13], saliency detection problem has been solved using graph based manifold ranking. In [14], a color and spatial contrast based saliency model is presented which uses four corners of an image to detect the image background. That method was inspired by reverse-management methods and it also applied energy function to further optimize foreground and background.

In [15], a regional contrast based saliency detection method is presented. They show that there are local and global contrast based saliency detection methods. Local contrast based methods commonly produce higher saliency values near object edges and fail to highlight the entire salient region. On the other hand, they criticized some global contrast based methods for being insufficient to analyse common variations in natural images. Inspired from biological vision they propose a histogram-based contrast method and a region based contrast method including spatial information for saliency detection.

In [16], the authors have proposed a saliency detection approach based on maximum symmetric surrounds. They used the low level features of luminance and color. They narrow down the search area for symmetric surrounds as they approach the borders. The disadvantage of their method is that if the salient region touches the border or is cut by the border, it cannot detect it and is treated as the

background.

So, there are biologically inspired methods and computationally optimized methods, local and global contrast based methods. There are also combinations of biological and computational models. In [17], a biology based method is used in [18] to extract the feature map and they used graph based approach to normalize the output. Some of the methods computed the entire feature map or some combined multiple maps to produce the final saliency model.

According to the previous discussion, it is obvious that the main challenges of saliency detection problem are low color dissimilarity of objects with its surrounding regions, size and position of a salient region in an image, computational complexity and usability of the method in real life applications. In this study, a combination of seam and color map based salient region detection technique is presented. The proposed method is easy to implement and does better than the other compared methods in response to the mentioned challenges. Details of the proposed method are presented in the following section.

3 Proposed Method

In this study, a novel approach is presented that combines seam and color map based saliency detection procedures in addition to traditional contrast and boundary prior based methods. Moreover, introduction of the quadratic equation based optimization method has improved the result significantly.

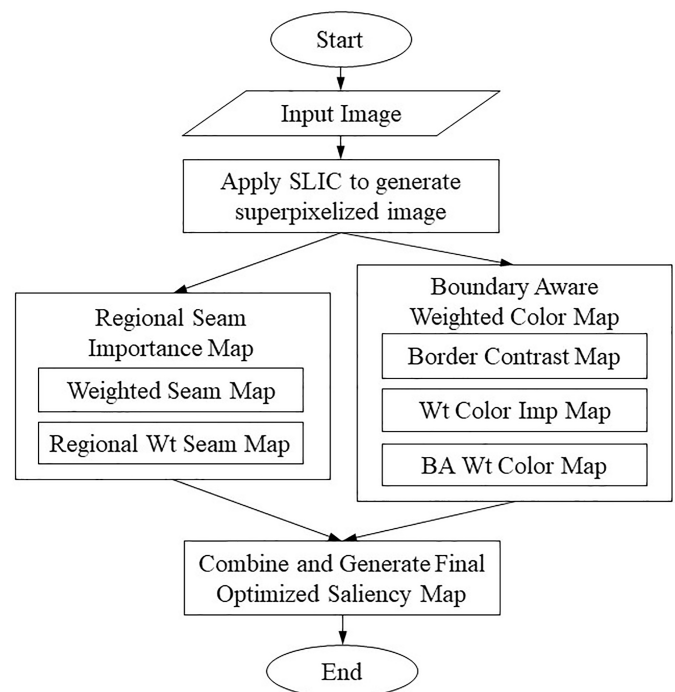

Figure 1: Flow chart of the proposed method.

Structure of the proposed method is shown in the flowchart of Figure 1. The raw input image is transformed into superpixel image. Seam and color importance maps are generated from this superpixelized image. These two saliency maps are then combined and optimized using a suitable optimization procedure to generate the

Figure 2: The SLIC approach to transform the input image into superpixels.

final saliency map. There are more internal steps seen in the flow chart. In this section the components of this flowchart are discussed in details.

3.1 Superpixel Image

At first, the input image is converted into superpixels using the SLIC method [19]. It groups similar pixels together using some clustering methods around randomly chosen pixel centers. Each region contains the averaged pixel intensity value in that region. It is done to speed up the calculation procedure. Since, working in pixel level will require more time to complete the calculation, it assigns a region ID to each pixel and computation can be continued using those regions only. By doing that the calculation becomes faster and quality is not much considered. It can be converted into the full size image anytime. Our main goal is to detect the salient region only. So, pixel level perfection is not necessary. Figure 2 depicts

how an input image is transformed into its superpixel form. Figure 2(b) shows the cluster boundaries which are generated from Figure 2(a). The final superpixelized image will look like the region base image of Figure 2(c).

3.2 Seam Importance Map

Seam map is computed from the energy map of a given image. It is the cumulative sum of minimum energy values from all four directions of an image namely top to bottom, left to right, bottom to top and right to left. Unlike [6] which computed a seam for the whole image, we follow [7] to get the seam for each pixel of the superpixelized image. The energy function is defined by Sobel operator to get the gradient image using eq. 1 which minimizes the cost. Here, the seam is an optimal 8-connected path of pixels. The superpixelized input image taken as the input to the seam map generation process following [5]. It produces better results as compared

Figure 3: Various stages of seam map calculation method.

Figure 4: Example of simple and complex border regions.

to [8] which uses the raw input image in the seam map generation procedure. The reason for this enhancement is the smoothness and stronger edges of the superpixelized image. The computation process is as follows: to compute the seam in the direction of top to bottom, each pixel follows eq. 2. The minimum cumulative sum of energy values of its previous row's 8-connected neighbours are summed up with the current pixel's energy value according to eq. 2 to calculate the current pixel's seam value. Other seam maps are generated in a similar fashion. Since, the background pixels take lower values in any of the four maps as seen in Figure 3, the minimum seam value at each pixel is taken in eq. 3 which suppresses the background well. This way the combined map is found by selecting the minimum of four values for each pixel by eq. 3. The seam map generation process of this study is presented in Figure 3 which shows that Figure 3(b), 3(c), 3(d) and 3(e) are computed from the energy image 3(a); and 3(f) is the combination of seams from Figs. 3(b), 3(c), 3(d) and 3(e). It removes the disadvantage of boundary prior and successfully enumerates the salient object even if it cuts the boundary of an image. The region level seam map is found by averaging seam values in each region as seen in eq. 4. The final seam map is generated by further down-weighting distant regions using average spatial distance as in eq. 5. Pictorial representation of the seam map generation process is visually presented in Figure 3. In this study this seam importance map is combined and further optimized intelligently to produce the final saliency model which does better in conditions where the salient region cuts the boundary.

$$\text{Energy Image, } e(I) = \left| \frac{\delta}{\delta x} I \right| + \left| \frac{\delta}{\delta y} I \right| \quad (1)$$

$$M_T(x, y) = \begin{cases} e(x, y); & \text{if } y = 0 \\ e(x, y) + \min[M_T(x-1, y-1), M_T(x-1, y), M_T(x-1, y+1)]; & \text{otherwise} \end{cases} \quad (2)$$

$$\text{Imp}_{seam}(x, y) = \min[M_L(x, y), M_T(x, y), M_R(x, y), M_B(x, y)] \quad (3)$$

$$\text{Imp}_{seam}(r_i) = \frac{1}{|r_i|} \sum_{\forall I_{est}(x,y)=i} \text{Imp}_{seam}(x, y), \text{ where} \quad (4)$$

$|r_i|$ = Number of pixels in region r_i

$$S_{seam,s}(r_i) = \frac{\text{Imp}_{seam}(r_i)}{d_s^2(r_i)} \quad (5)$$

$d_s = \|p_i - p_j\|$, Euclidian region distance where p_i, p_j is mean position vector for r_i, r_j

3.3 Border Contrast Map

Boundary prior is a very successful cue in case of saliency detection. Many researchers have found this cue useful in generating state of the art results. It mainly assumes that boundary regions are mostly backgrounds. This can be easily understood by examining the simple examples and their surroundings in Figure 4. In that figure, the backgrounds of both 4(a) and 4(b) have similar colors like the border regions. Although, Figure 4(a) is simple and have a background similar to the border regions and Figure 4(b)'s boundary regions have several color intensities but all of them constructs the boundary and significantly differ from the salient object or region. To get advantage of this simple but significant characteristic of a digital image, every region is compared with the border regions to find the dissimilarity of that region with the image boundary. In eq. 6 these contrast dissimilarities are computed and the border contrast map is found by averaging the dissimilarities of each region with all boundary regions using eq. 7.

$$\rho(r_i, b_j) = 1 - \exp\left(\frac{-d_c^2(r_i, b_j)}{\sigma^2}\right) \quad (6)$$

d_c = Euclidian color distance
 σ = constant to control strength
 $b_j = j^{th}$ region of total P border regions

$$S_B(r_i) = \frac{1}{\alpha P} \sum_{k=1}^{\alpha P} B_i(k) \quad (7)$$

$B_i(k) = \rho(r_i, b_j)$, Dissimilarity vector for r_i
 α = constant $0 < \alpha < 1$

3.4 Color Importance Map

A color map in this study consists of the weighted average of different color channels in CIE Lab color space. In a digital image most of the image pixels are backgrounds. So, the main idea of

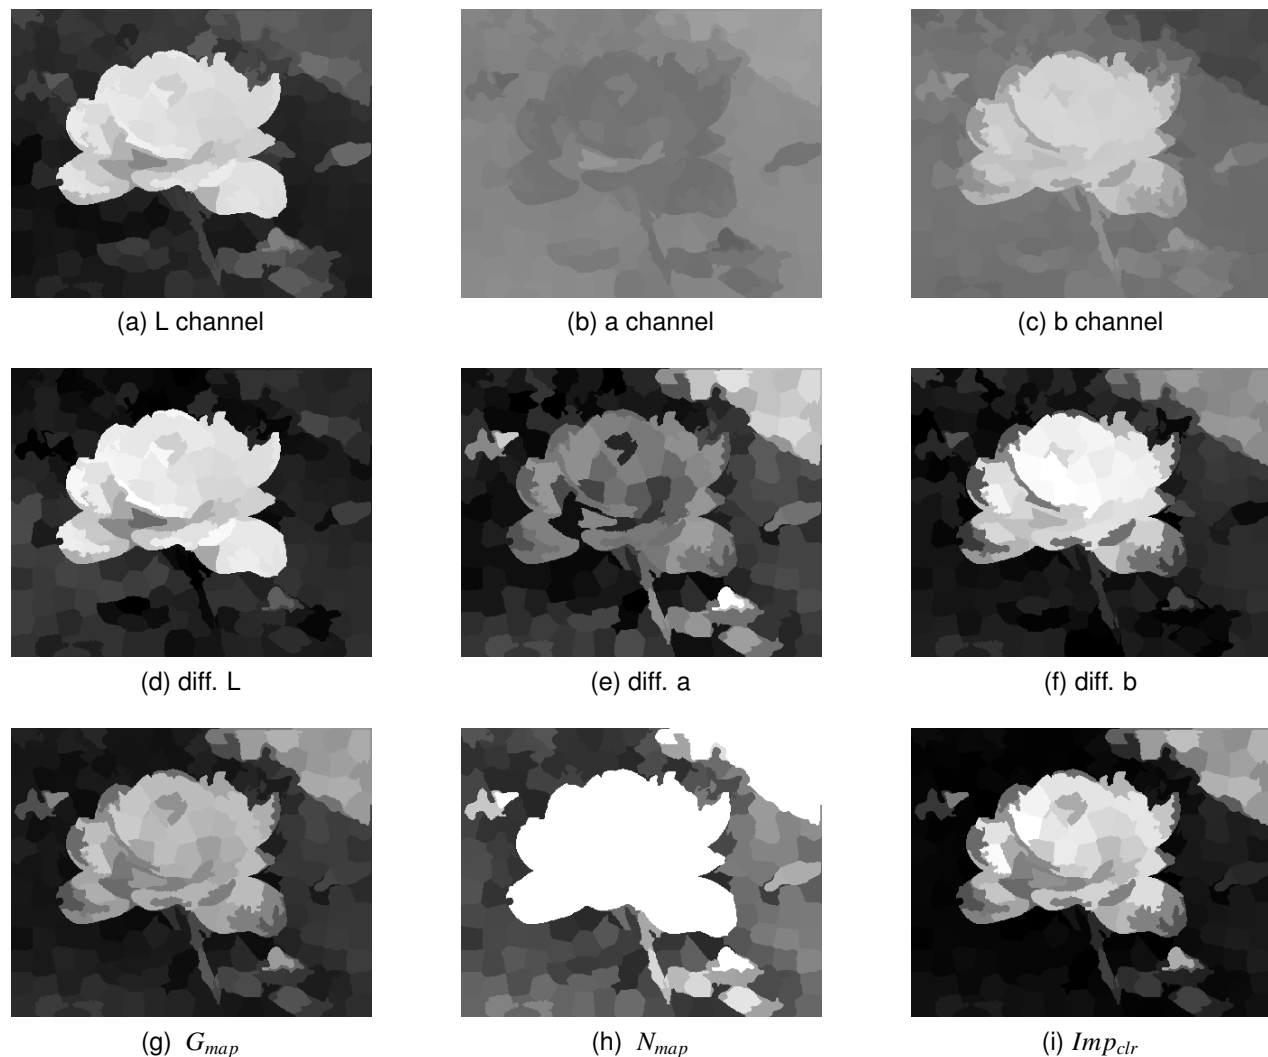

Figure 5: Various stages of computing color map.

color importance map is to suppress those background pixels by applying some weighting techniques so that the salient regions become prominent. The device independent Lab color space is used to calculate the weighted color map. Because, it provides us more information than RGB color space where all three channels contain similar information. The average L, a and b channels are calculated using eq. 8 and the color difference images are found by subtracting each channel's average from color intensity values of each pixel as of eq. 9. The visual model of different Lab channels are given in Figure 5. In that figure, the color difference images of Figure 5(d), 5(e) and 5(f) shows remarkable contrasts than its corresponding raw channel images of Figures 5(a), 5(b) and 5(c). The average calculation of the L channel is a bit different. Because, in this channel the intensity values can differ in a range of 0 to 255. Thus the mean and mode can have a large difference and because of frequency, the mode may become insignificant. For this reason, the minimum of $(L_{mean} + L_{mode})/2$ and L_{mean} is taken as the weighted average in eq. 8. The Grey map (G_{map}) in eq. 10 sums up all three channels and Normalized map (N_{map}) in eq. 11 produces the magnitude value of the color space. These two maps are combined into a single

saliency map using eq. 12. Though, gamma correction improves the result very slightly, it is performed on the grey map before the combination in eq. 12 as seen in Figure 5(i). The pixel level color map is transformed into a region level map using the region average in eq. 13. The combined map highlights the salient region significantly, but it also fails at image boundary. So, the border contrast map is introduced with weighted color map in eq. 15 to produce the boundary aware color importance map. 6 shows the boundary aware version of the color importance map. As seen in this figure, the boundary aware color map of Figure 6(c) is found by merging border contrast map of Figure 6(a) and seam map of Figure 6(b). The resulting combination is a better candidate for saliency detection.

Figure 6: Boundary aware color importance map.

Figure 7: Combination of boundary aware color map and seam map.

$$\begin{aligned} C_{avg} &= [L_{avg}, a_{avg}, b_{avg}] \\ L_{avg} &= \min\left(\frac{L_{mean} + L_{mode}}{2}, L_{mean}\right) \\ a_{avg} &= \frac{a_{mean} + a_{mode}}{2} \\ b_{avg} &= \frac{b_{mean} + b_{mode}}{2} \end{aligned} \quad (8)$$

$$\begin{aligned} S_{clr,s}(r_i) &= \frac{Imp_{clr}(r_i)}{\frac{1}{N} \sum_{k=1}^N d_s(r_i, r_k)} \\ d_s &= \text{Euclidian region distance as in eq. 5} \\ N &= \text{Number of regions} \end{aligned} \quad (14)$$

$$\begin{aligned} dI_{Lab}(x, y) &= |I_{Lab}(x, y) - C_{avg}| \\ I_{Lab}(x, y) &= \text{Color intensity of pixel}(x, y) \text{ Lab image} \end{aligned} \quad (9)$$

$$\begin{aligned} S_{bClr}(r_i) &= S_B(r_i) \times [1 + S_{clr,s}(r_i)] \\ S_B(r_i) &= \text{Border contrast map from eq. 7} \end{aligned} \quad (15)$$

$$\begin{aligned} G_{map}(x, y) &= w_L d_L(x, y) + w_a d_a(x, y) + w_b d_b(x, y) \\ \text{where, } w_L &= 0.1 \text{ and } w_a = w_b = 0.45 \end{aligned} \quad (10)$$

$$N_{map}(x, y) = \sqrt{d_L^2(x, y) + d_a^2(x, y) + d_b^2(x, y)} \quad (11)$$

$$\begin{aligned} Imp_{clr}(x, y) &= G_{map}^\gamma(x, y) \times N_{map}(x, y) \\ \text{where, } \gamma &= 1.5^{-1} \end{aligned} \quad (12)$$

$$\begin{aligned} Imp_{clr}(r_i) &= \frac{1}{|r_i|} \sum_{\forall I_{clr}(x,y)=i} Imp_{clr}(x, y), \text{ where} \\ |r_i| &= \text{Number of pixels in region } r_i \end{aligned} \quad (13)$$

3.5 Combining Seam and Color Importance Maps

Following the traditional way of combining saliency maps, the boundary aware color importance map is combined with seam importance map by eq. 16 using multiplication as seen in Figure 7. The combined saliency map of Figure 7(c) is found by merging boundary aware color map of Figure 7(a) and seam map of Figure 7(b). The samples in Figure 7(a) and Figure 7(b) both contain highlighted portions of backgrounds. Though the combined result in Figure 7(c) successfully suppresses the background, it does not enumerate the salient result sufficiently. So, an optimization procedure is required to do the rest of the job.

$$Sal'(r_i) = S_{bClr}(r_i) \times S_{seam,s}(r_i) \quad (16)$$

3.6 Color Distance and Contrast Dissimilarity

The existing color contrast between the regions in an image is one of the main attractions of saliency detection studies. The euclidean color distance in the Lab color space of the superpixels is used to measure the contrast difference between the superpixels as in eq. 17. The global contrast map is found by using eq. 18. This is used in the optimization equation as the smoothness weight.

$$\rho(r_i, r_j) = \exp\left(\frac{-d_c^2(r_i, r_j)}{\sigma^2}\right)$$

$$d_c(r_i, r_j) = \sqrt{(c_i - c_j)^2} \quad (17)$$

c_i, c_j = Mean color vector of r_i, r_j
 σ = constant to control strength

$$S_G(r_i) = \frac{1}{N} \sum_{k=1}^N \rho(r_i, r_j) \quad (18)$$

N = Number of regions

3.7 Optimization

Most of the previous researchers use multiplication or weighted summation to combine multiple saliency cues. The resulting combination does not do well in case of generalization. The main objective of saliency detection techniques is to generate a map closer to the binary ground truth image. So, some authors developed an optimization technique towards this goal. In this research, optimization is done by minimizing their quadratic cost function 19 proposed in [2]. All three terms of this cost function are square errors and it can be solved by using least square method. The first term of the cost function represents the background which forces a superpixel p_i with greater background weight w_i^{bg} to take a small value s_i closer to 0. In this research, the background weight w_i^{bg} is $1 - Saliency$. The second term represents the foreground which forces a superpixel p_i with greater foreground weight w_i^{fg} to take a value closer to 1. Here, the foreground weight is one of the saliency maps found in this study. The third term is the smoothness term which smooths both the background and foreground by removing small noises. The color dissimilarity based global contrast map from eq. 18 is used as the weight for the smoothness term. Since the target of this weight is to smooth the combined saliency map, connecting two levels of nearest neighbours and the boundary regions before dissimilarity measures produces better results. In this study, different combinations of saliency measures are used as the foreground and background weight in eq. 19 as shown in table 2 and a balanced combination is proposed as the optimal combination. The optimal saliency map of Figure 8(c) is found by solving the quadratic equation proposed in [2] using 8(a) as background map and 8(b) as foreground map.

$$\sum_{i=0}^N w_i^{bg} s_i^2 + \sum_{i=0}^N w_i^{fg} (s_i - 1)^2 + \sum_{i,j} w_{i,j} (s_i - s_j)^2 \quad (19)$$

4 Experiments and Results

4.1 Datasets

Standard datasets like MSRA 1k, MSRA 10k, CSSD and ECSSD are used to evaluate the performance of this study. Here, MSRA 1k and 10k are subsets of widely used MSRA original dataset which contains 20,000 images along with their hand labelled rectangular ground truth images which are manually annotated by 3-9 users. In [20] and [21], the authors has claimed that the original MSRA dataset has limitations in fine grained evaluation because of being too coarse in some cases. In [21] the authors presented the MSRA 1k or ASD dataset by manually segmenting each salient region which overcomes the limitations of the original MSRA dataset. An extended version of MSRA 1k dataset which contains pixel level binary ground truth images of 10,000 images from the original MSRA dataset is presented in [15]. They named this dataset MSRA10k which was previously called THUS10000. The first row of Figure 9 shows some bounding box annotation from original MSRA dataset and the second row shows the pixel level ground truth annotation from MSRA10k dataset. Almost all modern saliency detection techniques use this dataset as a benchmark for evaluation of saliency detection methods.

MSRA based datasets are good for saliency detection evaluation and contain a large variety in contents, but their backgrounds are relatively simple and smooth. To evaluate the complex situations in saliency detection, where objects and backgrounds have relatively low contrast and object surroundings are comparatively complex, in [12] the authors have proposed CSSD dataset with pixel level binary ground truths in 2013 which is a more challenging dataset with 200 images containing complex situations and they extended the dataset by increasing the images to 1,000 in [22] and named it Extended Complex Scene Saliency Dataset (ECSSD). Some members of CSSD and ECSSD datasets with complex backgrounds and low contrast surroundings are presented in Figure 10.

Table 1: Datasets and compared methods.

Dataset	Compared Methods
MSRA 1k	CA[23], FT[24], HC[15], LC[25], MSS[16], GS[1], SF[10], SWD[26], BARC[3], BARCS[8], BACS[5]
MSRA 10k	GS[1], SF[10], BARC[3], BARCS[8], BACS[5]
CSSD	GS[1], SF[10], BARC[3], BARCS[8], BACS[5]
ECSSD	GR[27], IT[17], SR[28], MSS[16], GS[1], SF[10], BARC[3], BARCS[8], BACS[5]

4.2 Evaluation Metrics

There are usually two types of evaluation strategies for every computer vision technique - qualitative analysis and quantitative analysis. Results found in this study are compared with several state of the art methods which are labelled as HC[15], MSS[16], GB[18], SWD[26], RC[29], AC[30], IT[17], GR[27], LC[25], FT[24], CA[23], AIM[31], GS[1], SF[10], SR[28], BARC[3], BARCS[8] and BACS[5]. Most of these labels are used in previous researches like [21], [15] and [32]. Other labels are constructed by taking some meaningful letters from the titles of the related publications.

Figure 8: Combination of foreground and background maps to generate the optimal saliency model.

Figure 9: Rectangular annotation of original MSRA dataset and the pixel level ground truth annotation from MSRA10k dataset.

Based on publicly available results for specific dataset, the proposed method has been compared with other state of the art methods as shown in Table 1.

Qualitative analysis of this study are presented in Figure 15 and 16 with some of the mentioned methods containing comparative samples from respective technologies. For quantitative analysis precision recall curves are shown for different datasets along with other techniques that clearly proves the superiority of the proposed method. To draw this precision recall curve simple binarization is performed by varying the threshold in the range from 0 to 255 and the curves are plotted according to the ground truth data available for each input image in the corresponding dataset. Since the only consideration of precision-recall curve is whether the foreground region saliency is higher than the background saliency, to evaluate the overall performance F-beta measures in Figure 14 are also presented in this study to better understand the performance of the compared methods.

4.3 Experimental Setup

Standard datasets are used to evaluate the proposed method. An initial 600 pixel region size is considered for converting the input image into the superpixelized version using the SLIC method. Other static variables are considered as $\alpha = 0.25$ and *compactness* = 20.

4.4 Optimization Experiments

Some promising combinations of saliency maps are explored in this study which are briefly discussed in this section. In the proposed optimization method, if the border contrast map is used as the background weight and the seam importance map is used as the foreground weight, we find closer PR curves as seen in Figure 12. The f-beta score is also closer to the proposed method as depicted in that figure. Similarly, different combinations are experimented for this study. Some of them are presented in table 2 and their qualitative and quantitative results are shown in Figure 11 and Figure 12 respectively. The runtime for these three combinations are given

Figure 10: Some members of CSSD and ECSSD datasets with complex backgrounds and low contrast surroundings.

Figure 11: Optimization combinations.

in table 3. In all three combinations, the smoothness weight is kept the same which is the global contrast map between the superpixels from eq. 18.

From the results in Figure 11, 12 and runtimes in table 3 it is seen that all three compared methods are closer to each other. But the second combination is the slowest since it introduces more computational complexities and the first combination is the fastest in terms of runtime comparison. On the other hand, for the MSRA 1k dataset the second combination does well in case of PR curve and F-beta test. But, the third one does well in complex situations like the ECSSD dataset. Its performance is also competitive in MSRA 1k dataset and the runtime is quite acceptable in comparison to the fastest method and its excellent performance on the complex dataset. Thus the third combination is chosen as the proposed method in this

study and it will be termed as *Our* method onwards.

Table 2: Proposed optimization combinations.

Method	Foreground	Background
Comb1	Border Contrast Map from eq. 7	Seam Map from eq. 4
Comb2	Border Contrast Map from eq. 7	Combined Seam and Boundary Aware Color Map from eq. 16
Comb3 (Proposed)	Boundary Aware Color Map from eq. 15	Weighted Seam Map from eq. 5

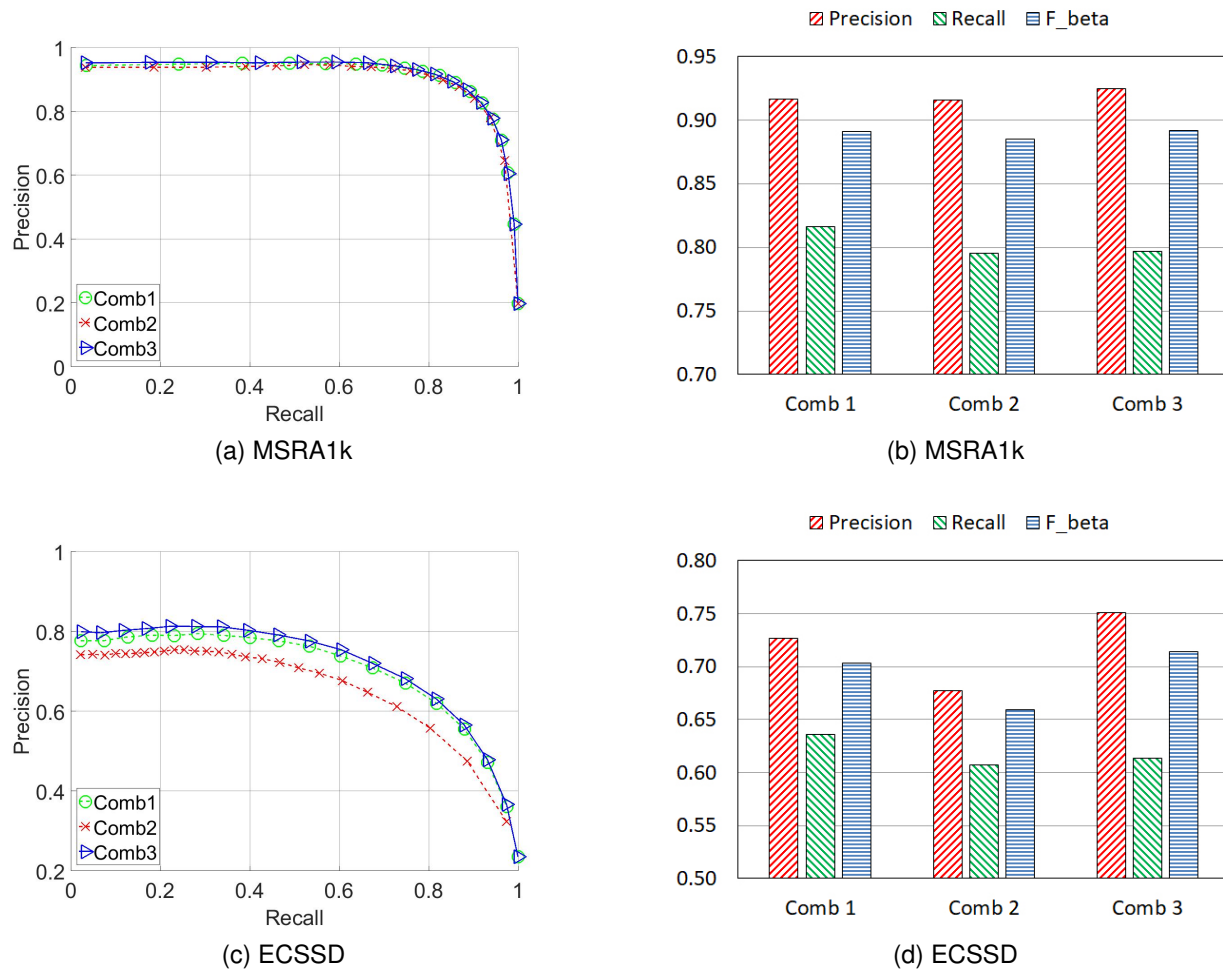

Figure 12: Precision recall curves for different combinations.

Method	Comb1	Comb2	Comb3 (Proposed)
Time (sec)	1.63	2.65	1.745
Code	Matlab	Matlab	Matlab

4.5 Results

The qualitative analysis in Figure 15 and 16 visually demonstrates the performance of the presented method compared to other state of the art techniques. The first row shows the input images and the last row contains the target pixel level ground truths for corresponding input images. From those figures it is seen that the proposed method done quite well with respect to other compared techniques.

In case of quantitative comparison, the precision-recall curve in Figure 13 clearly demonstrates the superiority of the proposed method. As pointed in [15], all methods have the same precision and recall values at maximum recall for threshold = 0 and all pixels are considered to be in the foreground. On the other hand, if the curves are observed from recall value 0.5 to 1, it is realized that for all datasets the proposed method exhibits higher precision values

due to smoother saliency containing more pixels in the salient region with saliency value 255 until it reaches to the common minimum precision value at recall = 1 and distinctly remains at the top of other curves until that. When a PR curve shows higher precision values for higher recalls, that is considered better. So, for the given datasets the proposed method clearly outperforms all other methods in terms of PR curve analysis.

$$F_{\beta} = \frac{(1 + \beta^2) \text{Precision} \times \text{Recall}}{\beta^2 \times \text{Precision} + \text{Recall}} \quad (20)$$

To measure the overall quantitative performance F_{β} measures are also calculated. In doing so, $\beta = 0.25$ is considered in eq. 20 like [8] and [3] to draw F-beta measures in Figure 14. The bars in this figure demonstrate that the presented method clearly surpasses other state of the art techniques.

The average runtime of different methods are given in table 4 as presented in [15]. The given times are dependent on the programming platform and different machine specifications. It may vary on other computer or programming platforms. So, this is mentioned here only for references. The average runtime of the proposed method is also mentioned in that table. The configuration of the

5 Conclusion

A novel method of saliency detection is presented in this paper that combines seam and color map based saliency detection procedures. The background and foreground weights proposed for the quadratic eq. 19 have successfully outperformed other state of the art methods and those have never been explored before. Some intermediate combinations are also presented with their detailed comparison. Though, one of the combinations is marked as the proposed solution balancing the runtime and performance, any of them can be used

with respect to the application demand. Moreover, the presented results in the experimental section of this study clearly demonstrates the superiority of the proposed method over other state of the art techniques in terms of qualitative and quantitative analysis. The use of standard benchmark datasets strengthens the acceptability of this study and its publicly available results make an opportunity for other researchers to compare their findings with the proposed method.

Computational devices are improving day by day. So, in future exactness of saliency detection technique will be the main concern. Moreover, a fine tuned version of the proposed method is possible and its implementation in an application level programming language like C++ would certainly improve its runtime. Besides that, different saliency weight calculation procedures of this study like border contrast map, color map and contrast based dissimilarity can be parallelized and this way runtime can come to its minimum. So, the future plan is to improve the saliency detection technique performance and apply it into various computer vision related applications like pedestrian detection, action recognition, object detection and recognition etc. Experimenting the proposed model with more complex datasets can be another interesting scope of study.

6 Declaration

6.1 Availability of data and materials

The experimental results of this study are available for download at (<https://aminulislam.net/#research>). The famous MSRA 10k dataset is freely available at (<https://mmcheng.net/msra10k>), the CSSD and ECSSD datasets are available at (<http://www.cse.cuhk.edu.hk/~leojia/projects/hsaliency/dataset.html>). Other datasets used and/or analyzed during this study are available from the authors upon reasonable request.

6.2 Competing interests

The authors declare that they have no competing interests.

6.3 Authors' contributions

AI executed the experiments, analyzed results, and wrote the initial draft of the manuscript. SMMA contributed to the concept, edited the manuscript, supervised the project and provided technical sup-

port and conceptual advice. The authors reviewed and approved the final manuscript.

6.4 Acknowledgements

We thank all the people who gave us various perceptive and constructive comments.

CMOS Current conveyor

ABSTRACT

The design of microelectronic systems is often complex, therefore metaheuristics can be of a great interest, because in most cases these systems have conflicting objectives and constraints. In this paper, we demonstrate the application of multi-criteria design strategies to a CMOS current conveyor. This provides designers with the ability to develop solutions that can meet several objectives respecting the design constraints. Therefore, three evolutionary algorithms well-known for their best performance in the resolution of more difficult multi-objective problems are proposed. They are first applied to the well-known benchmark functions and then for the optimal design of the current conveyor transistors in the framework of the 0.18 μ m CMOS technology. The aim is to maximize the bandwidth and minimize the parasitic input resistance respecting the technological constraints of the circuit. The obtained results are integrated in Cadence tool to show their validities. Final performances obtained by the three methods are in agreement and are better compared to the state-of-art-results.

1 Introduction

Today, with the complex growth of VLSI technology, it is very difficult to hand design analog integrated circuits with multiple parameters and purposes. The characterization of complicated trade-offs between conflicting and nonlinear performances while ensuring the required design specifications makes the design of analog circuits a tedious and time-consuming process. In this regard, due to their design difficulty and complexity, analog circuits have been attracted a lot of optimization attention. In general, optimization is often a time-consuming process having several contradictory criteria as well as a wide variety of design parameters. However, the design of electronic circuits is carried out by optimizing the circuit parameters to be able to rapidly design high-performance circuits [1]. For instance, finding passive elements values and transistor sizes and bias currents, so it can meet output performances such as gain, frequency band, power consumption, etc.

Several metaheuristics have been developed in the literature, which can be divided into two principal categories [2]: Single solution based methods, such as Taboo Search (TS) [3], Local Search (LS) [4], Simulated Annealing (SA) [5], or population based approaches like, Ant Colony Optimization (ACO)[6], Whale Op-

timization Algorithms (WOA)[7], Grey Wolf Optimizer (GWO), Particle Swarms Optimization (PSO)[8], Hybrid PSO-GWO [9], Non-dominated Sorting Genetic Algorithm (NSGA II)[10], Multi-objective Genetic Algorithm (MOGA)[11], Strength Pareto Evolutionary Algorithm (SPEA2)[12], etc. Single solution based techniques do not offer good results for problems where different types of variables, objectives and constraint functions (linear or non-linear constraints) are used [8]. Moreover, their efficiency highly depends on their parameters, the search space dimension and the number of variables. The population based techniques are generally classified into two groups, Particle Swarms (PS) and Evolutionary Algorithms (EA). PS give good results for problems that are not so difficult [13], but their performance also depends on their parameters and the complexity of the problem, especially for multi-objective optimization problems (MOP) [5, 13]. However, EAs are optimization techniques based on biological evolution and natural selection of species [14], are population-based, where each individual represents a possible solution. The initial population is generated randomly. At every new generation, the population iteratively evolves by the mutation, the crossover and the selection operators on each individual, and only non-dominated solutions meeting the constraints, will survive. Hence, such algorithms are well-known for their efficiency when

^{*}Corresponding Author: Abdelaziz Lberni, abdelaziz.lberni@usmba.ac.ma

solving complex MOP, Unlike PS, EAs do not need big parameter adjustments.

In this paper, we apply EAs for the optimal design of the current conveyor (CCII). The used EAs are NSGA II, MOGA and SPEA2, which allows the simultaneous optimization of multiple conflicting targets resulting into a set of Pareto Front (PF) solutions. Hence, the main objective to optimize the size of the MOS transistors transistors, using these algorithms, to achieve the high performances of the CCII. The CCII is one of the best known current mode circuits, making it the objective of several applications, such as filters, oscillators, etc., [15]. As far as we know, few works have been reported until now on CCII optimization by the EAs. In [16], the MOPSO with Crowding Distance (CD) was used for the optimization of the CCII, the differential CCII and the current feedback operational amplifier (CFOA) for low voltage low power applications, the MOPSO-CD was used as a part of a simulation-based tool to find the optimal sizing transistors that operate in weak inversion. In [17], the NSGA II and the decomposition-based multi-objective EA (MOEA/D) were used for the optimization of other purposes of the CCII, i.e., current gain and offset. However, the high-performance CCII design requires that the input parasitic resistance be small and its cut-off frequency be high. For this reason, we have chosen in this work these two characteristics as objectives to be optimized. All EAs generate Pareto fronts and simulations are carried out on Cadence using 0.18 μ m CMOS process. The simulation results are conform to those obtained by the optimization.

This paper is structured as follows: Section 2 gives an overview of the EAs, Section 3 is dedicated to the EAs validation using usual test functions. Section 4 presents the CMOS CCII. Section 5, is devoted to the results and discussion. A conclusion is given at the end.

2 Evolutionary Algorithms

2.1 MOGA

The MOGA was introduced in [11], as a new variant of the Golberg approach [18]. It uses the concept of dominance and a random-based fitness assignment. The non-dominated solutions are ranked into groups, which are assigned the same rank in each group.

The pseudo-code of MOGA is given by algorithm 1.

Algorithm 1: MOGA Pseudo Code

```

Generate the initial population  $P_i$ ;
Evaluate of  $P_i$ ;
while the stopping criteria is not met do
     $i=i+1$ ;
    Selection of  $P_i$ ;
    Mutation and Crossover of  $P_i$ ;
    Evaluate  $P_i$ ;
end
Result: non-dominated solutions

```

2.2 NSGA II

NSGA-II, which was proposed in [10] as a modified version of NSGA, is among the most commonly used and effective EAs due to

its simplicity and effectiveness. The basic operation of the NSGA-II is : A random population is created. This generated population is sorted using the notion of dominance. A fitness function is assigned to each solution. Therefore, it is assumed that physical fitness is minimized. At first, selection, mutation and crossover operators are used to create a new population from the first. The NSGA II algorithm uses the notion of elitism, to compare the current population with previously found best non-dominated solutions.

NSGA II relies on two major procedures: crowding distance and fast non-dominated sorting. Both procedures ensure elitism and feasibility of solutions. Algorithm 2 represents the NSGA II pseudo-code.

Algorithm 2: NSGA II Pseudo Code

```

Generate randomly the initial population  $P_1$ 
while the stopping criteria is not satisfied do
    while population in not classified do
        Search for non-dominated individuals;
        Fitness calculation;
        Sharing;
    end
    Mutation;
    Crossover;
    Selection;
end

```

2.3 SPEA2

SPEA2 is a MO algorithm introduced in [12] as an improved version of SPEA. It is based on the notion of dominating fitness evaluation to to generate the PF. SPEA2 uses elitist concept maintaining an external archive of non-dominated solutions. It also uses a nearest neighbor density estimation method, and an improved archive Truncation approach.

The SPEA2 is given by algorithm 3.

Algorithm 3: SPEA2 Pseudo Code

```

Generate randomly population  $P_i$ ;

3 EA robustness

Before using the proposed algorithms, we evaluated performances using multi-objective standards ZDT functions [19].

Each ZDT function includes two objectives f_1 and f_2 with 30 variables, which demonstrates the high complexity of such test functions. All tests are carried out with the algorithms parameters of

1000 iterations and a population size of 50 and a crossover probability of 0.8 and a mutation probability of 0.1. The ZDT benchmark functions and their expressions are given in the appendix.

Figure 1 shows the PFs obtained for the three chosen algorithms. As can be clearly seen the generated PFs with the all proposed methods achieve good approximations to the exact benchmark functions PFs. Therefore, we can confidently use them for the optimization problems of the CCII optimal design with guaranteed results.

4 CMOS Current Conveyor

In this section, we studied the current conveyor shown in Figure 2, it has three active ports X, Y and Z, and its main function consists of

- Current follower between ports X and Z, which can be provided by the translinear loop formed by transistors M1- M4.
- Voltage follower between ports X and Y, which can be provided by M5-M6 and M7-M8 current mirrors.

The present current conveyor topology is the most used one for its good performances and the interest of using a translinear loop [20]. Therefore, the design optimization of the CCII is performed considering its main objective functions : the parasitic resistance at the port X (R_X) and the cut-off frequency (f_{-3dB}). Recall that the aim is to minimize the first objective to obtain low input resistance and to maximize the second objective to get high bandwidth.

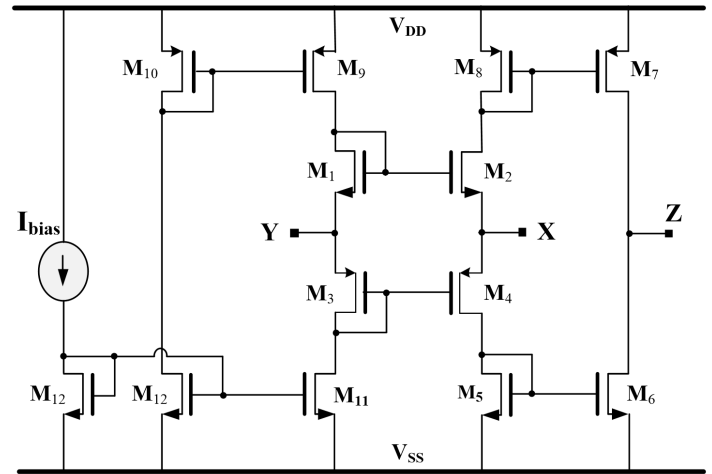

Figure 2: CMOS Current conveyor.

The CCII sizing is performed as in [14], using CMOS 0.18 μm process, and with the following conditions $V_{DD} = V_{SS} = \pm 1.8\text{V}$. All the transistors are characterized by their geometrical parameters: the channel length L and the gate width W .

The CCII optimal sizing issue is treated as a MOP. The aim is to find the best trade-off between a small R_X and a high f_{-3dB} as a function of the transistors parameters. The problem constraints are given by Eqs. 4 and 5 below corresponding to the saturation transistor regime [15].

The design problem can be formulated as:

$$\begin{aligned} \text{Minimize } & R_X(x) \text{ and } -f_{-3dB}(x). \\ & x = \{W_n, W_p, L_n, L_p, I_0\}. \end{aligned}$$

(1)

subject to

$$g_{1,2}(x) \leq 0,$$

where

- The resistance R_X is

$$R_X = \frac{1}{g_{mn} + g_{mp}} = \frac{1}{\sqrt{2\mu_n C_{ox} \frac{W_n}{L_n} I_0} + \sqrt{2\mu_p C_{ox} \frac{W_p}{L_p} I_0}} \quad (2)$$

$g_{mn(p)}$ is the transconductance for N(P) channel transistor. μ_n (μ_p) and C_{ox} are the electrons (holes) mobility and the gate oxide capacitance per unit area, respectively. I_0 is the bias current.

- The cut-off frequency f_{3dB} is

$$f_{3dB} = \frac{\omega_{3dB}}{2\pi} \quad (3)$$

The saturation constraints g_1 and g_2 are given by :

- The constraint of M_2 and M_8 transistors:

$$g_1 = V_{SS} - V_x(min) + V_{tn} + \sqrt{\frac{2I_0}{\mu_n C_{ox} \frac{W_n}{L_n}}} + \sqrt{\frac{2I_0}{\mu_p C_{ox} \frac{W_p}{L_p}}} \quad (4)$$

- The constraint of M_4 and M_5 transistors:

$$g_2 = V_x(max) - V_{DD} - V_{tp} + \sqrt{\frac{2I_0}{\mu_n C_{ox} \frac{W_n}{L_n}}} + \sqrt{\frac{2I_0}{\mu_p C_{ox} \frac{W_p}{L_p}}} \quad (5)$$

where $V_{tn}(V_{tp})$, $V_{DD}(V_{SS})$ are the threshold voltage for NMOS(PMOS) and the supply voltage, respectively. W_n (W_p), L_n (L_p) are the gate width and the channel length for n-channel (p-channel) transistors, respectively.

5 Results and discussion

All the CCII transistors with the same channel type have the same parameters (W_n , L_n for NMOS and W_p , L_p for PMOS). To respect the industrial design constraints, we also used identical channel length (L) for all transistors.

5.1 CCII optimization results

The optimal MOS transistors sizes are reached using EAs by minimizing R_X and maximizing f_{3dB} in two ways:

First, the optimization process is performed by MOGA, SPEA2 and NSGA II using three I_0 values, i.e., 20 μ A, 40 μ A and 80 μ A. For these experiments, we use the minimum channel length $L_n = L_p = L_{min}$. The generated PFs (R_X and $-f_{3dB}$) by the algorithms for different bias currents are shown in Figure 3. From this figure, we can see that the best trade-off between R_X and $-f_{3dB}$ is obtained for the PF with the large bias current $I_0=80\mu$ A. Therefore, designers have to select the best trade-off solution depending on the circuit design and its application requirements.

Figure 3: Pareto fronts obtained by the three algorithms for three bias currents

Second, the optimization process is performed by the same algorithms using three channel lengths L_{min} , $2L_{min}$ and $3L_{min}$. For these experiments, we use $I_0 = 80\mu$ A. The generated PFs for these cases are shown in Figure 4. From this figure, we can see that the best trade-off between performances is achieved for the PF with a minimum channel length L_{min} . Unlike digital circuits, the channel length for analog circuits is usually at least $3L_{min}$, which is why we tested all three channel lengths. This relatively large channel lengths minimizes the effects of channel modulation.

Figure 4: Pareto fronts obtained by the three algorithms for three channel lengths.

Based on the results in both scenarios, we can see that the best performances are obtained with a smaller channel length and a higher bias current. Considering the effects of channel modulation, power consumption and the circuit design and application requirements, IC designers should select the appropriate solution.

We run all algorithms 10 times, to evaluate the weakness and strength of each algorithm in all the performed experiments. To evaluate the diversity and the distribution of Pareto solutions, we

use the hyper volume metric [21]. This metric shows the covered area by the Pareto front. In case of minimization, of the problem, the larger hyper-volume value, the good is the quality of Pareto front solutions.

The hypervolume results are shown in Table 1. The optimization procedure required a mean CPU time of approximately 6.707 s, 67.25 s, and 148.412 s for NSGA II, MOGA and SPEA2, respectively.

Compared to the others algorithms, the NSGA II has the rapid CPU time and a good convergence rate confirmed by the higher hypervolume value.

Table 1: The Hypervolume Values.

		SPEA2	MOGA	NSGA II
L_{min}	20 μ A	0.750	0.752	0.752
	40 μ A	0.825	0.824	0.826
	80 μ A	0.873	0.875	0.876
80 μ A	1 L_{min}	0.873	0.875	0.876
	2 L_{min}	0.824	0.823	0.825
	3 L_{min}	0.782	0.784	0.785

5.2 CCII validation results

Table 2 presents the solutions to be validated by the CADENCE tool, they are defined by their cutoff frequencies, their values of R_X and the corresponding transistors parameters. They are randomly chosen from the PF that corresponds to $I_0 = 80\mu$ A and $L_n=L_p=L_{min}$.

Table 2: Parameters to be validated by Cadence, obtained in the PF that gives the best trade-off (R_X, f_{-3dB}).

	Test	$W_n(\mu$ m)	$W_p(\mu$ m)	f_{-3dB} (GHz)	$R_X(\Omega)$
MOGA	1	1.08	4.26	5.11	926.5
	2	3.77	13.38	3.08	481.26
SPEA2	1	0.86	3.54	5.63	1018.6
	2	4.30	17.85	2.66	439.07
NSGA II	1	0.80	3.08	6.04	1073.3
	2	4.65	15.77	2.64	443.26

Figures 5–8 show the simulation results of the selected solutions in table 2. The maximum (minimum) deviation between the simulation and the theoretical results is 10.1% (1%) and 9.4% (4.7%) for R_X and f_{-3dB} , respectively. This interval of variations is quite narrow and makes it possible to consider that the simulation results are in good agreement with the theoretical ones, obtained by the algorithms.

Table 3 presents a qualitative comparison of the obtained CCII performance with works previously published but with 0.35 μ m process. From the data given in this table, it is clear that the achieved performances are higher than reported, i.e, very higher frequency and much lower power consumption and good X-port resistance.

6 Conclusion

In this paper, we presented the usefulness of applying EAs, namely MOGA, SPEA2 and NSGA II, for the automatic optimization of high performances CCII. Several optimization experiments were carried out with three bias currents and three channel lengths, minimizing the parasitic resistance and maximizing the cut-off frequency. In all experiments, the achieved results show that these methods can provide Pareto Fronts with greater solutions diversity. The simulations are performed by Cadence using the CMOS 0.18 μm process, showing good accuracy with the theoretical results. The best performances achieved with EAs in this work can be summarized in a power consumption of 288 μW , a minimum parasitic resistance of about 247 Ω and a maximum frequency of about 6.04GHz.

Appendix

- ZDT1 function:

$$g(\vec{x}) = 1 + 9 \sum_{i=2}^{Dim} \frac{x_i}{30-i} \quad \text{and} \quad h(\vec{x}, f_1, g) = 1 - \sqrt{\frac{f_1(\vec{x})}{g(\vec{x})}} \quad (6)$$

$$f_1(\vec{x}) = x_1$$

$$f_2(\vec{x}) = g(\vec{x}) \cdot h(\vec{x}, f_1, g)$$

- ZDT2 function:

$$g(\vec{x}) = 1 + 9 \sum_{i=2}^{Dim} \frac{x_i}{30-i} \quad \text{and} \quad h(\vec{x}, f_1, g) = 1 - \left(\frac{f_1(\vec{x})}{g(\vec{x})} \right)^2 \quad (7)$$

$$f_1(\vec{x}) = x_1$$

$$f_2(\vec{x}) = g(\vec{x}) \cdot h(\vec{x}, f_1, g)$$

- ZDT3 function:

$$g(\vec{x}) = 1 + 9 \sum_{i=2}^{Dim} \frac{x_i}{30-i}$$

$$h(\vec{x}, f_1, g) = 1 - \left(\frac{f_1(\vec{x})}{g(\vec{x})} \right) \sin(10\pi f_1(\vec{x})) - \sqrt{\frac{f_1(\vec{x})}{g(\vec{x})}} \quad (8)$$

$$f_1(\vec{x}) = x_1$$

$$f_2(\vec{x}) = g(\vec{x}) \cdot h(\vec{x}, f_1, g)$$

Linguistic Analysis

ABSTRACT

Software maintenance contributes the majority of software system life cycle costs. However, existing approaches with automated code analysis are limited by accuracy and scope. Using human-assessed methods or implementing quality standards are more comprehensive alternatives, but they are much more costly for smaller organizations, especially in open-source software projects. Instead, bugs are generally used to assess software quality, such as using bug fixing time as an estimate of maintenance effort. Although associated bug reports contain useful information that describe software faults, the content of these bug reports are rarely used. In this paper, we incorporate quality standards with natural language processing techniques to provide insight into software maintainability using the content of bug reports and feature requests. These issues are classified with an automated approach into various maintainability concerns whose generalizability has been validated against over 6000 issue summaries extracted from nine open source projects in previous works. Using this approach, we perform a large empirical study of 229,329 issue summaries from 61 different projects. We evaluate the differences in expressed maintainability concerns between domains, ecosystems, and types of issues. We have found differences in relative proportions across ecosystem, domain and issue severity. Further, we evaluate the evolution of maintainability across several versions in a case study of Apache Tomcat, identifying some trends within different versions and over time. In summary, our contributions include a refinement of definitions from the original empirical study on maintainability related issues, an automated approach and associated rules for identifying maintainability related quality concerns, identification of trends in the characteristics of maintainability related issue summaries through a large-scale empirical study across two major open source ecosystems, and a case study on changes in maintainability over versions in Apache Tomcat.

1 Introduction

Software maintainability measurements provide organizations with a greater understanding of how difficult it is to repair or enhance their software. The importance of having this understanding is underscored in [1], which reported that 75-90% of business and command&control software and 50-80% of cyber-physical system software costs are incurred during maintenance. In addition, maintainability serves as a crucial link to other quality characteristics. In [2], the author lists maintainability as a contributing quality to life cycle efficiency, changeability and dependability. In [3], the maintainability is a key quality in understanding software quality interrelationships. Thus, having comprehensive knowledge of soft-

ware maintainability is significant in the software development and maintenance process.

A number of metrics and approaches have been developed to provide ways to measure and evaluate software maintainability. In this study, they are classified into the following categories:

- Automated analysis: Automatic analysis involves analyzing source code or other software artifacts and quantifying software maintainability into numeric results. This includes static code analysis such as measuring Maintainability Index, technical debt, code smells, and other Object-Oriented metrics [4, 5], as well as bug-focused metrics such as bug fixing time [6] and accumulated defect density [7].

^{*}Corresponding Author: Celia Chen, Email: qchen2@oxy.edu

- Human-assessed analysis: Human-assessed analysis includes reuse cost models that estimate maintainability of potentially reusable components based on human-assessed maintainability aspects, such as code understandability, documentation, and developer self-reported surveys [8, 9].
- Software ontology, standards and frameworks: These introduce immense high-level knowledge, which are mostly coming from consensus wisdom, professional discipline and expert sources. This includes standards such as the ISO/IEC 25010 and Software Engineering Body of Knowledge.

While the automated analysis metrics are easy to use and often require relatively low human effort, in [10] author points out that the effective use of accuracy measures for these metrics has not been observed and there is a need to further validate maintainability prediction models. Moreover, despite having the advantage of identifying the particular parts of the software most needing maintainability improvement at the module and method level, they do not provide an overall quality status for the current version of the software.

Although bug fixing times may reflect maintenance effort [6], these bug-focused metrics also do not provide a systematic understanding of software maintainability. Furthermore, these metrics do not utilize the information provided by the natural language descriptions due to their unstructured nature.

On the other hand, human-assessed analyses are able to more accurately reflect maintenance effort, yet they are limited in use due to cost and subjectivity based on developers' skills and experience [8, 11].

Software ontology, standards and frameworks tend to be used in larger organizations as guidelines during the development process. They provide insightful knowledge in understanding, evaluating, and improving a system's maintainability planning, staffing, and preparation of technology for cost-effective maintenance. However, it is very difficult to enforce standards on actual program behavior. Moreover, while standardizing the process can help make sure that no steps are skipped, standardizing to an inappropriate process can reduce productivity, and thus leave less time for quality assurance. Especially in smaller organizations and open source ecosystems, it is extremely difficult to apply and enforce these paradigms due to their limited resources and functionality-focused nature.

To provide a way to effectively measure and keep track of the overall maintainability while involving relatively low human effort, we utilize bug report information in conjunction with a software maintainability ontology to assess software maintainability at the system level in an initial empirical study [12]. By manually mapping over 6000 bug reports to maintainability subgroup software qualities (SQs) in the ontology, we validated the approach to evaluate overall system maintainability. However, this approach is limited by the amount of manual effort needed for mapping the bug reports. To overcome the high effort requirements, we incorporate natural language processing techniques to automatically classify "issue summaries," which include the descriptions of bug reports and feature requests, to the maintainability subgroup SQs. In this paper, we provide a refinement of definitions from the original empirical study on maintainability related issues and the rule set. We expand upon the scale of the analysis done in [12], made possible

by the fuzzy classifier, to identify trends in maintainability related issue summaries from two major open-source software ecosystems. We further perform an in-depth case study on the maintainability changes over versions and time in Apache Tomcat. In total we classify 229,329 issue summaries from 61 projects and the trends over 7 versions and 20 years in Apache Tomcat.

The rest of this paper is organized as follows. Section 2 summarizes related work and presents the differences of those compared to our study. Section 3 describes the background of the automated approach and introduces the research questions and design of an empirical study on maintainability trends in two open-source software ecosystems. Section 4 discusses the results, analysis and implications. Section 5 concludes the study.

2 Related Work

2.1 Software Maintainability Measurement

Maintainability Index (MI) is the most widely used metric to quantify maintainability in software projects. Since its introduction in 1992 [13], several variations have been developed [14, 15]. While it is widely used, the metric's effectiveness has been brought into question and several shortcomings identified [16].

Other approaches to measuring maintainability have incorporated other metrics as well as frameworks and ontology. In [17], the author provided an overview of an approach that uses a standardized measurement model based on the ISO/IEC 9126 definition of maintainability and source code metrics. These metrics include volume, redundancy, complexity and more.

In [18], the author investigated 11 different types of source code metrics in an empirical study to develop a maintainability prediction model for Service-Oriented software and compare their model with the Multivariate Linear Regression (MLR) and Support Vector Machine (SVM) approaches. They found that using a smaller set of source code metrics performed better than when they used all of the available metrics.

Approaches utilizing machine learning have also been proposed. In [19], the author conducted a comparative study on using machine learning algorithms for predicting software maintainability on two commercial ADA datasets. They examined Group Method of Data Handling, Genetic Algorithms, and Probabilistic Neural Network with Gaussian activation function for predicting a surrogate maintenance effort measure, the number of lines of code changed per class over a three year maintenance period. Their results showed improvement over previously reported models.

In [20], the author proposed an LSTM algorithm for software maintainability metrics prediction. They considered 29 OO metrics and applied their approach on a large number of open source projects. In addition to comparing against other machine learning algorithms, they also used FSS to determine which metrics are most relevant for maintainability prediction.

In [21], the author presented a study using several classifiers to evaluate maintainability at the class level using the output of different static analysis tools. In their approach, ConQAT, Teamscale, and Sonarqube are used to extract metrics such as SLOC, average method length, clone coverage, etc. The classifiers are trained using

expert-labeled data from three different systems. Their best results provided a classification accuracy of 81% and a precision of 80%.

2.2 Bug Characteristics Analysis with Natural Language Processing

Several studies have investigated the characteristics of bugs and bug reports through the use of natural language processing.

In [22], the author collected 709 bugs including security related and concurrency bugs. They analyzed the characteristics of those bugs in terms of root causes, impacts and software components. Their findings reveal characteristics of memory bugs, semantic bugs, security bugs, GUI bugs, and concurrency bugs. They verified their analysis results on the automatic classification results by using text classification and information retrieval techniques.

In [23], the author proposed an approach to binary classification of bug reports into ‘bug’ and ‘nonbug’ by leveraging text mining and data mining techniques. Analyzing the summary and some structured features including severity, priority, component, and operating systems, they use Bayesian Net Classifier as the machine learner. They performed an empirical study of 10 open source projects to validate their method and provide a MyLyn plugin prototype system that will classify given reports.

In [24], the author analyzed bug reports from nine systems and found that a large percentage of bug reports lack Steps to Reproduce (S2R) and Expected Behavior (EB) information. They in turn developed an automated approach to detect missing S2R and EB from bug reports. They produced three versions using regular expressions, heuristics and natural language processing, and machine learning. They found their machine learning version to be the most accurate with respect to F1 score, but the regular expressions and heuristics and natural language processing approaches had similar accuracy results without training.

In [25], the author constructed models for identifying security and performance related bug reports utilizing feature selection, random under-sampling, and Naive Bayes Multinomial approach. They evaluated their approach on datasets of bug reports from four software projects, achieving average AUC values of 0.67 and 0.71 for their security and performance models respectively.

Summing up, here is how our work differs from the existing studies: with regard to measurement of maintainability, our work enables study of maintainability evolution with relatively low cost. By using issues, preexisting software artifacts, it allows for expert knowledge to be applied to open source software systems wherein there is less control over development and maintenance tasks.

3 Empirical Study

3.1 Background

This section presents the software maintainability ontology used and an extension of the SQ definitions provided in [12]. It also provides a brief summary on our previous works and the overall automated approach.

3.1.1 Software Maintainability Ontology Background

The ontology provided in [2] presents maintainability as depending on two alternative SQs, repairability and modifiability, which handle defects and changes respectively. These SQs are further enabled by several subgroups. The automated approach focuses on maintainability in the context of these mean-ends SQs as shown in Figure 1.

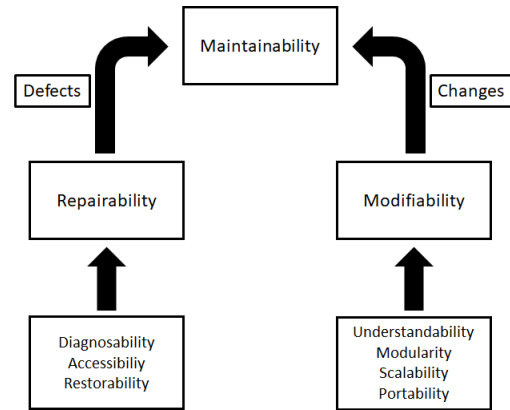

Figure 1: Software maintainability ontology hierarchy

The following are the refined definitions for each subgroup SQ to better capture the scope of these quality concerns.

Repairability involves handling of defects in software. It is enabled by the following SQs:

- **Diagnosability:**

Diagnosability is the characteristic of being diagnosable. It is the property of a partially observable system with a given set of potential faults, which can be detected with the certainty given finite observation. Issues that affect this SQ involve problems with lack of logging and diagnosability management, faulty error messages and the process of tracing where they originate, failure of tests, and insufficient information provided for accurate assessments [26]–[28].

- **Accessibility:**

Accessibility [29] generally describes the ability of a software system to accommodate people with special needs. This requires a software system to be suitable for most of the potential users without any modifications and be easily adaptable to different users with adaptable and customized user interfaces.

Another definition for accessibility is at the architecture level. The JCIDS manual [30] defines the Accessibility of Architectures as the ability to grant access to authorized users in a timely fashion in order to “support architecture-based analysis and decision making processes.” In this paper, accessibility is defined as the quality of being available and reachable, which involves whether the intended areas of a software system can be accessed as desired. Issues that affect this SQ prevent authorized users from accessing data or functions due to things such as redirects to unintended locations, broken links to intended areas, and incorrect user permission and authorization.

- **Restorability:**

Restorability describes the ability of a software system to restore to a previous state. Issues that affect this SQ include activities such as clearing of caches, refreshing settings, proper removal of data and backups of the current system.

Modifiability involves handling of software changes. It is enabled by the following SQs:

- **Understandability:**

Software understandability can be considered in the context of source code as well as non-source code artifacts and further depends on the person assessing the software. This may include the level of experience and familiarity with the software's code base if considering a developer's perspective or whether or not the software is clear in its usage and applicability if considering an end user's perspective. Understandability can have an impact on maintenance tasks especially in cases where the original developers are not the ones responsible for maintaining the system. Further explanation of software understandability is provided in [31].

Issues that affect this SQ involve activities such as system enhancement, lack of explanations and comments, confusing or inaccurate descriptions, presence of deprecated software and more.

- **Modularity:**

Modularity involves separation of code into modules. It indicates the degree to which a system's components are made up of relatively independent components or parts which can be combined [32, 33].

Issues that affect this SQ involve unwanted interactions between different modules and separation of one module into multiple modules.

- **Scalability:**

Scalability is the ability of a system to continue to meet its response time or throughput objectives as the demand for the software functions increases [34, 35]. Issues that affect this SQ involve latency in functionality, hangs, and insufficient resources for functionality to scale up or down.

- **Portability:**

Portability refers to the ability of a software unit to be ported to a given environment and being independent of hardware, OS, middle-ware, and databases [36, 37]. Issues that affect this SQ prevent proper interfacing between software components and external platforms.

3.1.2 Background Studies

In our previous empirical study [12], we manually analyzed 6372 bugs found in the Mozilla community. By categorizing them into one of the subgroup SQs described above, we identified various

trends in maintainability changes as software evolves and the relationships between these subgroup SQs. The findings were valuable but it was difficult to scale up the study due to the large amount of manual effort required to produce such mappings between bug reports and subgroup SQs.

Thus, a manual analysis on the ground-truth dataset¹ was first performed, and we identified three types of linguistic patterns from bug reports: lexical patterns, syntax patterns and semantic patterns. These patterns illustrate the recurrent linguistic rules that users are likely to use when reporting bugs or requesting new features. Motivated by these heuristic linguistic patterns, we proposed a fuzzy classifier [31, 38] that aims to identify the maintainability subgroup SQ concerns expressed in issue summaries. Based on the definitions of these patterns, a set of 24 initial fuzzy rules was generated by heuristically identifying them from subgroup SQ definitions and practice guidelines. To improve this initial fuzzy rule set, an incremental approach was constructed to identify potential new rules from issue summaries mined from four open-source projects. The rule performance was used to determine whether the existing rule set should be updated. As a result, we obtained a final set of 99 rules². To evaluate the generalizability of the obtained rule set, we evaluated it on projects that were not used in generating the rules. All metrics (accuracy, precision, recall, and f-measure) had an average above 0.8, indicating that the rule set is able to perform well in classifying issue summaries with all of the subgroup SQs. Thus, with such an automated classifier that can identify maintainability concerns expressed in issue summaries, we conduct a large empirical study to investigate the trends of maintainability across 61 open-source software projects and over 200,000 issue summaries.

3.2 Research Questions

To explore the characteristics of maintainability, we look to answer the following research questions:

- RQ1: How are software maintainability concerns expressed in different domains and ecosystems? For this RQ, each project is classified as one of the following:
 - Applications: these projects are designed to have some sort of direct interaction with general users [39]. Examples of these projects include web browsers, email clients, and office suites.
 - Infrastructure: these projects are not designed to interact with users directly. Instead, they provide facilities and services for other software to run [39]. Examples of these projects include build tools, web servers, and libraries.

To answer this RQ, we analyze the differences for subgroup SQs between these domains as well as between Apache and Mozilla projects.

- RQ2: How are software maintainability concerns expressed across different types of issues? For this empirical study, we report on the following characteristics:

¹Dataset can be found: <https://bit.ly/2WhWJx>

²The final rule set can be found: <http://bit.ly/3az2CRy>

- Won't Fix: Issues whose resolutions are WONTFIX have been classified such that they are not planned to be fixed. This can be for a variety of reasons, such as when the issue involves an unsupported method or tool, or when the issue is not worth the cost [40].
- Reopened: Issues that have been previously closed can be reopened in cases such as when new reproducibility information is reported, previous root causes are identified as misunderstood, reports with insufficient information are updated, or the priority of the issue has been increased [41].
- Unresolved: Some issues are left unresolved without updates. To investigate these unresolved issues, we filter the lists to identify issues whose status is not resolved or closed, and whose last changed or updated date is more than a year from June 30, 2020. This date is based on the point up to when the issues were collected.
- Severity: Issues are often classified depending on their impact, with most of the projects defining them as blocker, critical, major, etc. The MozillaWiki defines severity in terms of levels: S1, S2, S3, S4 for catastrophic, serious, normal, and small/trivial respectively; however, the previously mentioned descriptors are used more commonly. Thus for this RQ, the severities are defined as follows:
 - * Blocker: Blocker, S1
 - * Critical: Critical
 - * Major: Major, S2
 - * Others: All other categories

- RQ3: How does software maintainability change as software evolves?

To gain a better understanding of how maintainability changes as software evolves, we look to the issues of Apache Tomcat. This project has been selected as it has a long history: the Apache Bugzilla contains issues from Tomcat 3 to Tomcat 9, and it has versions separated to the patch level of granularity. To answer this RQ, we look at the data in three ways: by major version, within major version by year, and by year overall. The last updated date in the Apache Tomcat Archive is used to map each patch to a year. Evaluation by changes in minor version is not done as many versions have at most 2 minor versions for a given major version. In cases where versions have patch variants, such as release candidates or betas, the versions are combined. For example, Tomcat 4 has issues of version 4.0 Beta 1, Beta 2, etc. These are combined with the release candidates, milestones, and final version issues into a single 4.0.0 category.

3.3 Study Design

3.3.1 Study Subjects

This empirical study focuses on projects found within the Mozilla and Apache ecosystems. Table 1 provides the characteristics of the projects chosen for this study. Some projects are filtered out of the

study subjects. From Mozilla, projects from other and graveyard are excluded from the study as they contain many projects that do not focus on software. From Apache, projects that contain fewer than 100 issues are excluded. Apache OpenOffice and Apache SpamAssassin have their own Bugzilla repositories which are included with the other Apache projects.

3.3.2 Data Extraction and Analysis

Issue summaries from the selected projects are downloaded from their respective Bugzilla repositories along with the issue characteristics such as version, Open Date, etc. The issues are then classified as described in Section 3.1.2. They are then separated according to the criteria described in the RQs. Issues that are identified as invalid or duplicates are filtered out to avoid over-counting. For each SQ, the overall proportion is calculated from the number of expressing issues over the total number of issues to correct for differences in the number of issues reported between groups. Relative proportion is calculated from the number of expressing issues over the total number of issues that express any maintainability concern to compare how much each subgroup SQ contributes to overall maintainability.

In total, 229,329 issues are analyzed and classified as relating to one of the maintainability subgroup SQs or as non-maintainability. Of these, 82,577 (36%) are maintainability related and 146,752 (64%) are non-maintainability related. Figure 2 shows the relative and overall proportions of each of the maintainability subgroup SQs. The most prevalent maintainability subgroup SQs are understandability, portability, and accessibility.

4 Results and Discussion

4.1 RQ1

Of the 229,329 issues analyzed and classified, 180,706 come from Mozilla systems and 48,623 from Apache systems.

Table 2 compiles the number of issues expressing each SQ, the overall proportion of each SQ over the total number of issues, and the relative proportion of each SQ over the total number of maintainability issues.

Figures 3a and 3b show the proportion of issue summaries that express maintainability concerns across the chosen ecosystems and domains respectively. There is not a large difference between the proportion of maintainability issues when considering ecosystem or domain.

4.1.1 Overall Proportions

A MANOVA is performed to examine whether there is a significant association between the overall proportion of maintainability and each maintainability subgroup SQ with ecosystems or domains. More specifically, whether ecosystems or domains have a significant effect on the overall proportions of maintainability and each maintainability subgroup SQ. While there is a significant association found between ecosystem and the overall proportions of maintainability and its subgroup SQs, $F = 19.136$, $df = 8$, $p = 0.014$ (< 0.05), univariate analysis does not identify statistically significant SQs that contribute to the differences between ecosystems. In addition,

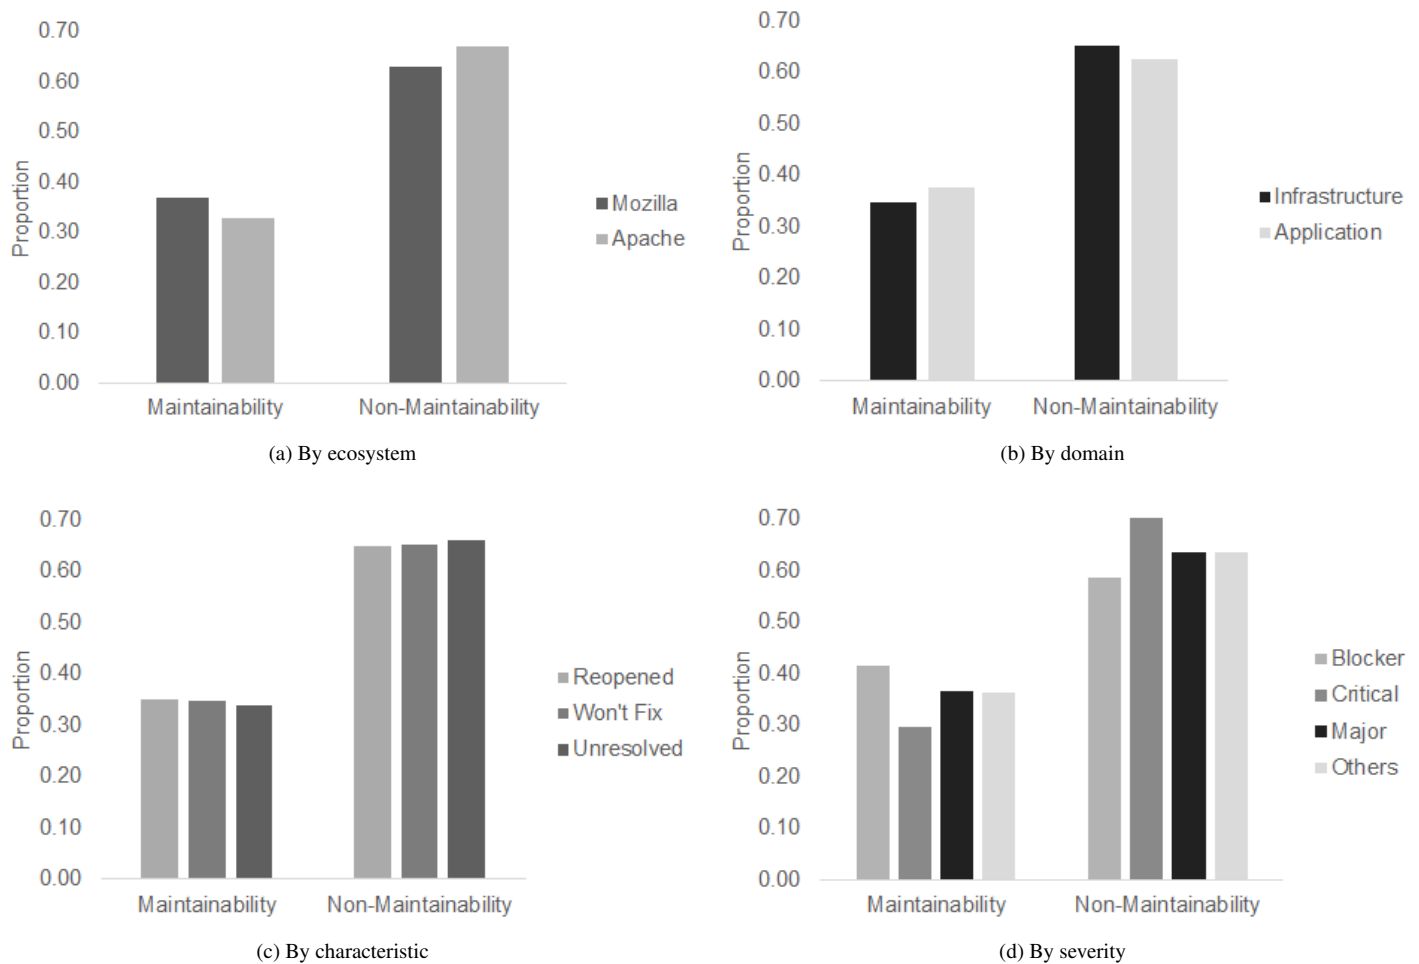

Figure 3: Distributions of maintainability versus non-maintainability issues

no statistically significant results are found for the overall proportions of maintainability and its subgroup SQs in terms of different domains, $F = 13.036$, $df=8$, $p=0.192$ (>0.05).

4.1.2 Relative Proportions

Pearson's Chi-squared tests are performed to examine whether the ecosystems or the domains are associated with the distributions of the relative proportion of each SQ. Overall, the distributions of the relative proportion of each SQ differ significantly in domains, χ^2 (6, $N = 61$) = 2226.5, $p < 0.001$; and also in ecosystems, χ^2 (6, $N = 61$) = 2921.2, $p < 0.001$.

As shown in Table 2, understandability, portability, and accessibility are most prevalent expressed concerns. When considering ecosystem, these SQs comprise the majority for both Mozilla and Apache; however, the Apache systems tend to express more accessibility concerns than portability concerns. In considering domain, the same three SQs are the most prevalent; however, for infrastructure type software, there tend to be more diagnosability issues and fewer relating to portability when compared to application type software.

Summary of RQ1: To summarize, in this study, there is a statistically significant association between ecosystem and the overall proportions of maintainability and its subgroup SQs. The distribu-

tions of relative proportions of subgroup SQs differ significantly between ecosystems and domains; there is a trend in application software which tends to have more portability issues and fewer diagnosability issues compared to infrastructure software. As application type software is targeted toward end-users, there may be a larger variety of use cases which would necessitate compatibility with other software. In contrast, infrastructure software is targeted toward developers. In this case, they may place more importance on being able to diagnose issues with the software and may already be aware of incompatibilities with other software.

4.2 RQ2

4.2.1 RQ2a: Reopened, Won't-fix and Unresolved

Of the 229,329 issues classified, 1,251 are marked as REOPENED, 16,909 are marked as WONTFIX, and 18,809 are identified as unresolved. Figure 3c shows the proportion of issue summaries that expressed maintainability concerns across these three categories. Similar to the overall proportion, these categories are comprised of about 35% maintainability issues.

Table 2 compiles the number of issues expressing each SQ, the overall proportion that these SQs make of all tagged issues, and

the relative proportion that these SQs make of all maintainability related issues across categories. For won't-fix and unresolved issues, understandability, portability, and accessibility make up the largest percentage of expressed maintainability concerns. For reopened issues, diagnosability replaces portability of the top 3 subgroup SQ concerns. Won't-fix issues tend to express more portability concerns with relatively fewer diagnosability concerns compared to the other two categories.

4.2.2 RQ2b: Severity

Comparing the number of issues within each category of severity, the issues are divided into 4887, 17799, 15424, and 191219 issues associated with Blocker, Critical, Major, and Others types respectively. Figure 3d shows the proportion of issue summaries expressing maintainability concerns across these different levels of severity. For the highest severity category, blocker, maintainability issues make up 41%. Interestingly, the relative proportion of maintainability issues decreases for the next severity category, Critical, to 30%, while increasing again to 36% in the Major and Others categories. Table 2 compiles the number of issues expressing each SQ, the overall proportion that these SQs make of all tagged issues, and the relative proportion that these SQs make of all maintainability related issues across severities.

Portability, accessibility, and understandability remain the most prevalent expressed SQs except for the Critical category, where understandability is replaced by scalability. Blocker and Critical issues have similar proportions of portability and accessibility issues while accessibility issues have higher prevalence in Major issues. Finally, the less severe Others category is comprised largely of understandability issues.

A MANOVA is performed to examine whether there is a significant association between the overall proportion of maintainability and each maintainability subgroup SQs with different levels of severity. There is a statistically significant association found between levels of severity and the overall proportions of maintainability and its subgroup SQs, $F = 166.42$, $df = 24$, $p < 0.001$. Of the subgroup SQs, accessibility, portability, scalability, and understandability are found to have statistically significant differences across severity levels, with $p < 0.001$ after Bonferroni correction.

Pearson's Chi-squared tests are performed to examine whether levels of severity are associated with the distributions of the relative proportion of each SQ. Overall, the distributions of the relative proportion of each SQ differ significantly across severity, $\chi^2 (18, N = 61) = 5795.8$, $p < 0.001$.

Summary of RQ2: To summarize, in this study, won't-fix and unresolved issues tend to express understandability, portability, and accessibility concerns. Reopened issues tend to express diagnosability concerns in addition to understandability and accessibility. For the case of won't-fix issues tending to express more portability concerns than the baseline-total, this result could be explained as portability issues involve factors external to the system. These types of issues are more likely to involve unsupported tools or potentially costly integrations, leading to a classification of WONTFIX.

The highest severity issues tend to have a higher proportion of maintainability issues than lower severity issues, and there is a significant association between levels of severity and the overall and

relative proportions of the different subgroup SQs. This finding validates our results from the previous empirical study. As these issues have a high impact on the system, this reinforces the importance of ensuring high maintainability to avoid these types of issues.

4.3 RQ3

4.3.1 Changes between major versions

When comparing between major versions, there does not appear to be a strong trend in terms of the percentage maintainability issues make of the total. Figure 4a shows the relative proportions of each subgroup SQ. There appears to be a decreasing trend for accessibility and an increasing trend for understandability related issues for later versions. Figure 4b shows the overall proportions of each subgroup SQ. In this case, the increase in understandability related issues continues.

4.3.2 Changes within major version by year

To provide an analysis of the relationship between the subgroup SQs and time, we map each patch to a year based on the last updated date in the Apache Tomcat Archive and perform linear regression within each major version. Figures 5a, and 5b show the statistically significant trends ($p < 0.05$) in relative proportions, overall proportions, and number of issues reported respectively. For clarity, the scales of the y-axes are set individually by version in Figure 6 due to relatively large differences in overall proportions and number of issues between versions.

- Version 3: Only restorability showed a statistically significant decline in number of issues reported. Relative and overall proportions did not have statistically significant relationships. We acknowledge that very few issues overall were reported in 2003 and 2004 which may contribute to this trend.
- Version 4: Other than modularity, all subgroup SQs showed statistically significant decline in number of issues reported. However, the decline in number of issues reported is also present for issues in general. In terms of relative proportions, accessibility and understandability showed declines while portability showed an increase over time. For overall proportions, accessibility, modularity, restorability, and understandability all showed declines. We acknowledge that very few issues overall were reported from 2005 to 2008 which results in the relative proportions of 0 for accessibility and understandability and the relative proportions of 1 in portability within those years. These values may skew the significance of the trends.
- Version 5: Portability and understandability showed statistically significant decline over years for number of issues reported. Those SQs showed similar declines, and accessibility showed statistically significant increase for relative and overall proportion of SQs.
- Version 6: Accessibility and portability showed a statistically significant decrease in number of issues reported over years.

Figure 4: Proportions by major version of Apache Tomcat

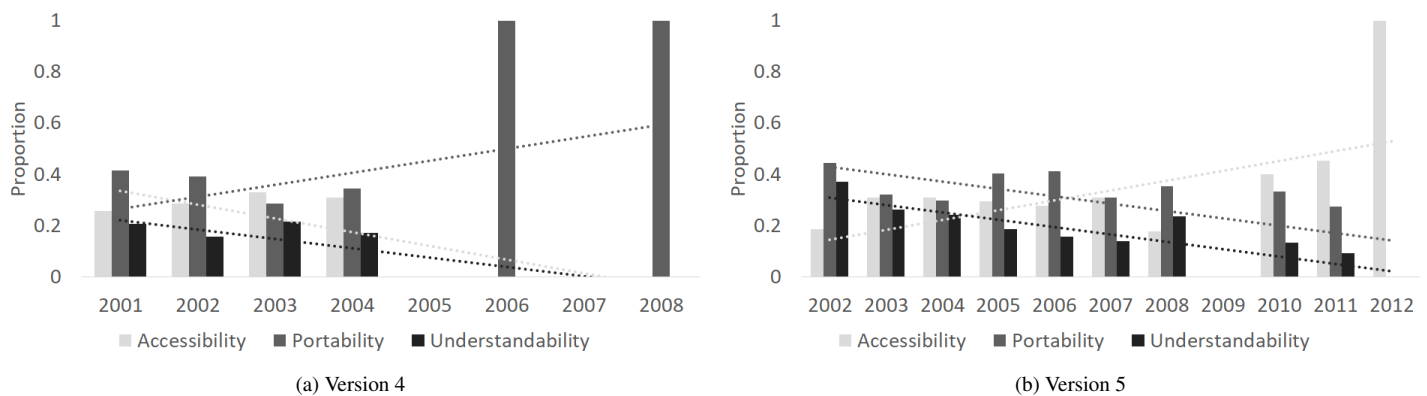

Figure 5: Statistically significant relative proportions of subgroup SQ concerns across years by versions

This was shared with the number of maintainability, non-maintainability, and total issues reported. No SQs were found to have a statistically significant change in relative proportion; however, the overall proportion of portability related issues increased.

- Version 7: Accessibility, portability, scalability, and understandability all had declines over time along with decreases in numbers of maintainability, non-maintainability, and total issues reported. Overall proportions of portability and maintainability had increases over time, but no trends were found for relative proportions.
- Version 8: Accessibility, portability, and understandability all had declines over time along with decreases in number of maintainability, non-maintainability, and total issues reported. No trends were found for relative or overall proportions.
- Version 9: No significant trends were found for version 9

4.3.3 Changes by year overall

When considering all issues by year, there is a general decline in the number of issues reported overall which is found for all SQs. This trend is found in general for the number of issues reported; Figure 6 shows the number of maintainability and non-maintainability

related issue summaries reported per year for Tomcat. However, when looking at the overall and relative proportions, there are no statistically significant trends across the SQs.

Summary of RQ3: To summarize, although there is not a significant trend in terms of the percentage of maintainability issues between major versions, there is a decreasing trend for accessibility while an increasing trend for understandability for later versions. In addition, various subgroup SQs show statistically significant trends in relative proportions, overall proportions and the number of issues reported.

While there are a number of statistically significant trends within versions, the most common is a decline in number of issues reported overall over time and within the versions themselves. Possible reasons for the decline in issues reported include that people are not reporting as many issues in general compared to in the past, the later versions are still being maintained and developed so there has been less time to report issues, and finally that the maintainability has increased over time.

As there are no statistically significant trends in terms of relative or overall proportions of the subgroup SQs when looking at changes by year overall, this may indicate that focusing on the greatest relative proportions overall (i.e. accessibility, portability, and understandability) will be effective regardless of time in the life cycle.

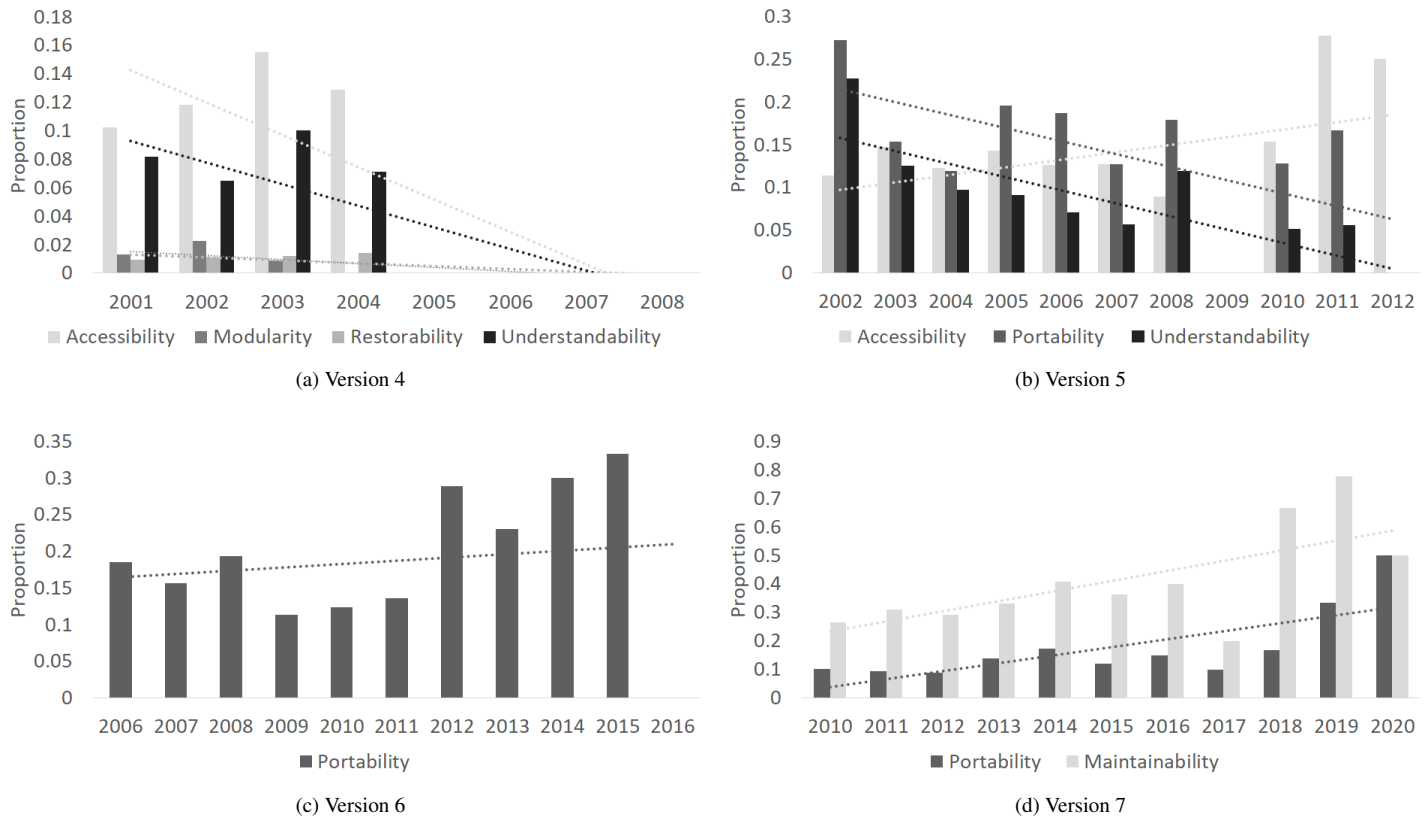

Figure 6: Statistically significant overall proportions of subgroup SQ concerns across years by version

4.4 Threats to Validity

This study depends on the model developed in [38]. The accuracy of classification is subject to the limitations and threats to validity detailed in the prior work.

Some information in issue summaries is self-reported by the developers of the different software projects such as severity, version information, etc. Validation of this information is out of the scope of this study; however, the developers reporting the issues are the most qualified to assess these metrics given their familiarity with the projects. Thus, we assume the reported information is correctly identified.

As our case study focused only on Apache Tomcat, our findings with regard to quality changes within versions and over the life of the project should not be generalized to other projects without further study.

5 Conclusion

Motivated by the lack of effective systematic measurement of maintainability in practice, we presented a novel approach to achieve automatic identification on how software maintainability and its subgroup SQs are expressed in a series of publications. Enabled by the automated approach to scale up analysis of maintainability through issue summaries, in this article, a large empirical study on 229,329 issue summaries from 61 different projects was conducted. Out of all the issue summaries, 82,577 issues were classified as expressing

maintainability concerns. These issues were further analyzed to evaluate the differences between domains, ecosystems, and types. We found differences in relative proportions across ecosystems, domain and issue severity. Additional analysis was performed on Apache Tomcat to evaluate the evolution of maintainability across several versions. We identified several trends within versions and over time, such as a general decline in the number of issues reported overall in all the subgroup SQs and a statistically significant decline in portability and accessibility in multiple versions.

We believe that our work introduces a new angle to the area of software maintainability evaluation, encourages researchers to utilize unstructured software artifacts, and promotes automated solutions to incorporate standards and frameworks into software development process.

Conflict of Interest The authors declare no conflict of interest.

ABSTRACT

In view of the current short-term traffic flow prediction methods that fail to fully consider the spatial correlation of traffic flow, and fail to make full use of historical data features, resulting in low prediction accuracy and poor robustness. Therefore, in paper, combining Non-negative Matrix Factorization (NMF) and LSTM model Based on Attention Mechanism (AttLSTM), the NMF-AttLSTM traffic flow prediction algorithm is proposed. The NMF algorithm is used to extract the spatial characteristics of traffic flow and reduce the data dimension. The attention mechanism can extract more valuable features from a long sequence of historical data. First, select high-correlation upstream and downstream roads, use NMF algorithm to perform dimensionality reduction and to extract historical data features of these roads, then combine with the historical data of this road as input. Finally, use the AttLSTM model to predict. Experiments with the PeMS public data set and Wuhan core roads data show that the method has higher prediction accuracy than other prediction models and is an effective traffic flow prediction method.

1 Introduction

Short-term traffic flow forecasting in Intelligent Transportation Systems (ITSs) has always been an important component.¹ Based on current and past traffic flow data, it can predict traffic flow ranging from a few minutes to a few hours in the future, providing a basis for decision-making for traffic dispatch and planning. Traditional traffic flow prediction models can be divided into two types, parametric and non-parametric. Parametric models include some time series models, such as Exponential Smoothing (ES), Autoregressive Integrated Moving Average (ARIMA)[2] model and Kalman Filtering model, etc. Non-parametric models include K-Nearest Neighbor (K-NN) method, Artificial Neural Network (ANN), and Support Vector Machine (SVM) [3]–[5] etc. However, because traffic flow data is affected by various environmental factors and has the characteristics of non-linearity and suddenness, the above models are affected by random factors and become fragile, which makes it difficult for these models to obtain high prediction accuracy. In recent years, deep learning has developed rapidly, and its applications have penetrated into all walks of life. Since the deep neural network used in deep learning can simulate deep complex nonlinear relationships through

hierarchical feature representation, it can extract hidden features in the data. Therefore, in line with the characteristics of traffic flow data, deep learning methods can be used to predict traffic flow.

Recurrent Neural Network (RNN) is a type of deep learning model that can effectively predict time series data. In recent years, many researchers have conducted in-depth research on its application and achieved many results. However, with the increase of the input time series length, the traditional RNN will have the problem of gradient explosion and gradient disappearance. It can only use the information on time steps close to itself. In [6], the author uses Long Short Term Memory Network (LSTM), which can effectively overcome the problems of gradient disappearance existing in RNN and capture the characteristics of time series in a longer time span. There are also many variants of LSTM networks. Gated Recurrent Unit (GRU) can be seen as a simplification of the LSTM network. It combines the forgetgate and input gate in the LSTM network into one gate unit, which simplifies the structure of the model. In [7], the author compared the performance of LSTM model and GRU model on short-term traffic flow. Although the above deep learning models have achieved good results on prediction tasks, they do not consider the spatial correlation between traffic flows, and the spatial

¹This paper is an extension of work originally presented in the 10th International Conference on Information Science and Technology (ICIST), 2020 [1].

topology of traffic sections has an important impact on traffic flow. Therefore, considering the temporal and spatial characteristics of traffic flow, [8] combines the Autoencoder and the LSTM model, and uses the Autoencoder to obtain the traffic flow characteristics of adjacent locations. The adjacent locations represent the upstream and downstream locations of the current location. The LSTM model is used to predict the traffic flow at the current location. However, using the autoencoder model to extract features requires pre-training of the data, which is time-consuming, and the LSTM model does not perform well when the historical input sequence is long.

In [9], the author uses the attention mechanism to perform translation and alignment at the same time on machine translation tasks. At present, it is believed that the paper applies the attention mechanism to the NLP for the first time. In [10], the author points out that attention mechanisms have been successfully combined with existing models in machine translation. In other areas, attention mechanisms have also been applied, for instance, [11] based on LSTM neural network combined with attention mechanism for visual analysis of human behavior. The paper [12] applied neural network based on attention mechanism to medical diagnosis. The attention mechanism can be understood as, for a long time series data, after calculating the correlation between each element and the current element, assigning different weights to these elements, used to measure their impact on the current element. We focus on those elements that have a greater impact on the current element.

Traffic flow data with typical time series characteristics can be predicted by the RNN model. In recent years, researchers have used this model to predict traffic flow. In view of the above-mentioned improvements of the RNN model in recent years, in order to further improve its predictive ability, based on the above research, a hybrid model traffic flow prediction method based on NMF-AttLSTM will be proposed. The method first uses the weekly average spatial correlation coefficient based on the Pearson correlation coefficient to filter the upstream and downstream roads, and uses the NMF algorithm to reduce the dimensionality of the historical data matrix composed of the filtered upstream and downstream data to obtain the reduced feature matrix. Compared with the Autoencoder, the NMF algorithm is fast, does not require a pre-training process, and is suitable for processing high-dimensional data. The advantage of using the LSTM model based on the attention mechanism is that for long historical input sequence data, it can measure the similarity between each historical data and the current observation, and determine the selection of features in the historical data according to the similarity. Compared with the LSTM model, its feature extraction method is more reasonable. The experimental results in this paper are based on the PeMS public data set [13] and the real traffic data of the core area of Wuhan. The effectiveness of the proposed method is verified by experiments on these two data sets.

The main work of this paper is as follows:

- Propose a method to extract the temporal and spatial characteristics of traffic flow, combine the upstream and downstream features of the current road segment, and use a non-negative matrix factorization algorithm to reduce the dimension of the data and extract the feature matrix.
- The attention mechanism is added to the LSTM model to enhance the predictive ability of the LSTM model.

- The NMF-AttLSTM model was verified using public data sets and real traffic data in Wuhan, and the experimental results proved the effectiveness of the method.

The rest of this paper is organized as follows. In the section II, the NMF algorithm is introduced first, and then the process of adding the attention mechanism to the LSTM model is given. Finally, the traffic flow prediction framework based on the NMF-AttLSTM model is proposed. In section III, Experiments were performed on two data sets and the experimental results were evaluated. The section IV summarizes the whole paper.

2 NMF-AttLSTM Traffic Flow Prediction Framework

2.1 Non-negative Matrix Factorization Algorithm

The traffic flow data is time series data, and the change patterns of the traffic flow of adjacent roads in the spatial position have high similarity, which implies the common characteristics of the traffic flow changes. In order to extract this specific feature, we can construct the historical traffic data on all relevant roads into a matrix form. As shown in the following formula, suppose there are related roads in total, and the time series length is t , and f_{ij} represents the traffic value of the road number i at time j .

$$F_{mt} = \begin{bmatrix} f_{11} & f_{12} & \dots & f_{1t} \\ f_{21} & f_{22} & \dots & f_{2t} \\ \dots & \dots & \dots & \dots \\ f_{m1} & f_{m2} & \dots & f_{mt} \end{bmatrix}, i \in [1, m] \quad j \in [1, t] \quad (1)$$

The NMF algorithm is used to analyze and decompose matrix data. Its definition is that for any given two-dimensional non-negative matrix, it can be decomposed into two non-negative submatrices to satisfy the multiplication of these two non-negative matrices to get the original matrix. As shown in (2).

$$F_{mt} = W_{mk} \times H_{kt} \quad (2)$$

Among them, W is called the basis matrix, and H is called the coefficient matrix or the characteristic matrix. In paper, the H matrix is used as the feature matrix of the original data to achieve the goal of dimensionality reduction and feature extraction. Since both W and H matrices are unknown, they need to be solved by algorithms. Although there are many ways to reduce the matrix dimension, we need to ensure that the values in W and H are non-negative, because all traffic flow values need to be non-negative.

Therefore, the NMF(F, k) algorithm is used to solve the characteristic matrix. At this time, the problem becomes that, given the original non-negative matrix and parameters, matrix factorization can be formulated as a non-negative factorization minimization problem[14]. As shown in the (3):

$$f(W, H) = \arg \min_{\{W, H\}} \|F - W \cdot H\|^2 \quad (3)$$

The NMF(F, k) algorithm first needs to define a cost function to quantify the degree of approximation between F and WH . One way is to use the square of the Euclidean distance between F and WH , as follows:

$$\|F - W \cdot H\|^2 = \sum_{ij} (F_{ij} - (W \cdot H)_{ij})^2 \quad (4)$$

Another way is to use Kullback-Leibler divergence (KL divergence) as the cost function, as shown in the (5):

$$D(F\| (W \cdot H)) = \sum_{ij} \left(F_{ij} \log \frac{F_{ij}}{(W \cdot H)_{ij}} - F_{ij} + (W \cdot H)_{ij} \right) \quad (5)$$

Since this paper needs to use the NMF algorithm to extract the flow characteristics of the relevant roads, it pays more attention to the distribution characteristics of the flow instead of the absolute difference in the flow value. And the KL divergence is often used to measure the similarity of the two distributions. Therefore, the KL divergence is selected as the cost function, and the problem of solving W and H is transformed into: Under the constraint condition $W, H \geq 0$, with W and H as parameters, minimize the cost function $D(F\|WH)$.

Use the multiplication update rule to iteratively update the parameters W and H . The update equation is as shown in the (6):

$$W_{ia} \leftarrow W_{ia} \frac{\sum_{\mu} H_{a\mu} V_{i\mu}}{\sum_{\mu} (WH)_{i\mu}} \quad H_{a\mu} \leftarrow H_{a\mu} \frac{\sum_i W_{ia} V_{i\mu}}{\sum_k W_{ka}} \quad (6)$$

In the above update rule, when W and H are at the stagnation point of the divergence formula, the divergence will no longer be updated. The proof of the convergence of the above update equation is given in [14]. Based on the NMF(F, k) algorithm, the basic matrix W and the corresponding feature matrix H are obtained. In the NMF-AttLSTM model, we mainly input H as a feature into the AttLSTM model to provide upstream and downstream spatial features for traffic flow prediction.

2.2 Construction of Attention-LSTM Model

LSTM is a recurrent neural network, as shown in Figure 1. RNN is usually used to deal with time series problems. RNN uses a series of historical data as input, extracts features through non-linear functions, and stores the features extracted from each layer to provide feature information for subsequent calculations. Circulation makes information continue to pass to the next layer.

Figure 1: Recurrent neural network (RNN)

However, compared with the conventional RNN, the structure of this repeated module A of LSTM is more complicated, as shown in Figure 2.

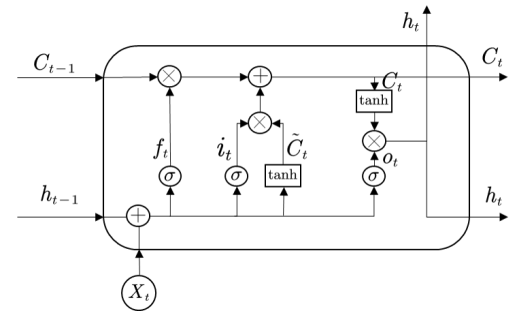

Figure 2: The structure of LSTM cell

This module consists of three parts, the forgotten gate, the input gate and the output gate. σ is the Sigmoid function, output a value between 0 and 1, describing how much of each part can pass.

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (7)$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (8)$$

$$\tilde{C}_t = \tanh(W_c \cdot [h_{t-1}, x_t] + b_c) \quad (9)$$

$$C_t = f_t \cdot C_{t-1} + i_t \cdot \tilde{C}_t \quad (10)$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \quad (11)$$

$$h_t = o_t \cdot \tanh(C_t) \quad (12)$$

Among them, f_t determines how much information we want to discard. i_t determines how much new information we should add. o_t determines how much information we want to output. x_t is the input at time t . h_{t-1} is the output of the previous gate, W_f , W_i , W_c and W_o is the weight, b_i , b_f , b_c and b_o is the bias, C_{t-1} is the cell state at the previous moment, C_t is the cell state at the current moment. Since the model is difficult to learn information at a time far from the current time, and it may be important for the current value. To overcome the weakness, we tried to add an attention layer to the LSTM network. Referring to the attention implementation steps of [10], we can apply it to the LSTM model. As shown in Figure 3, the attention layer is added to the LSTM model.

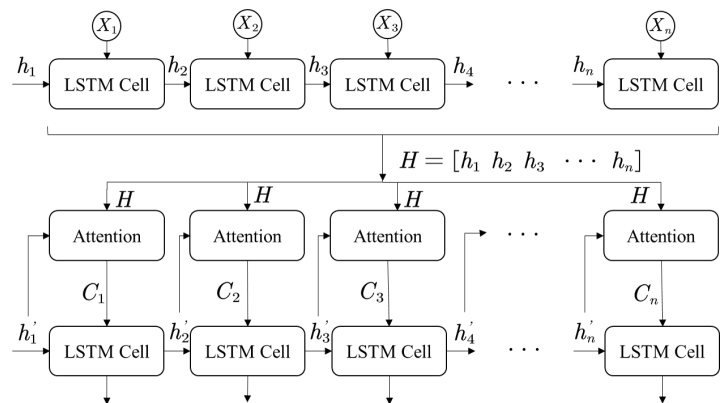

Figure 3: The process of adding an attention layer to the LSTM model

Among them, $X_i, i \in (1, n)$ is the input, h_i is the intermediate output result of each cell, all of h_i are input into each attention model as H , and the elements of the next layer h'_i are used as H'_i .

to calculate the similarity and weight coefficient, and finally get the attention coefficient. The specific attention model is shown in Figure 4.

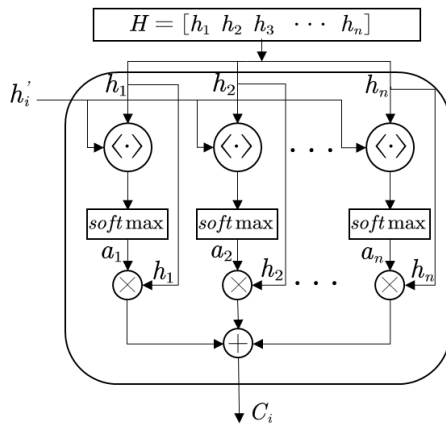

Figure 4: The internal structure of attention model

where $\langle \cdot \rangle$ represents the dot product operation, which is used to calculate the similarity between the current element and the intermediate output result in the previous layer, and then normalized by the softmax function to obtain the corresponding weight coefficient a_i . Finally, a weighted summation operation is performed to obtain the Attention value C_i . The equations used in the attention layer are as follows:

$$H = [h_1 \ h_2 \ \dots \ h_n] \quad (13)$$

$$\text{sim}_i = h_i' \cdot H^T \quad (14)$$

$$a_i = \frac{e^{\text{sim}_i}}{\sum_{j=1}^{L_h} e^{\text{sim}_j}} \quad (15)$$

$$C_i = \sum_{j=1}^{L_h} a_i \cdot h_j \quad (16)$$

In (14), it uses vector and to calculate similarity to obtain weights, (15) uses the softmax function to normalize the weight, (16) uses the normalized weight a_i and h_i weighted sum. The result of weighted summation is the attention weight value C_i . The implementation of the Attention layer is to retain the intermediate output results of the input sequence by the LSTM encoder, and then calculate the similarity between the intermediate output results of the previous layer and the current output to obtain the weight factor, and finally obtain the attention coefficient. Through the Attention mechanism, it is possible to find out the traffic flow in the past period that is most relevant to the forecast period in the time-based long traffic flow sequence, which improves the ability of the original model to predict a longer sequence traffic flow.

2.3 NMF-AttLSTM

In general, the traffic flow of a road is not only related to its own historical flow, but the flow of its upstream and downstream roads in space also has an important impact on the changes in its own flow. Full consideration of the flow changes in the upstream and

downstream roads is of great significance to the current road flow prediction. The definition of the upstream and downstream roads in the spatial position of a road is as follows: based on the direction of vehicle movement, all roads connected to the entrance of the road are called upstream roads, and all roads connected to the exit of the road are called downstream roads, As shown in Figure 5.

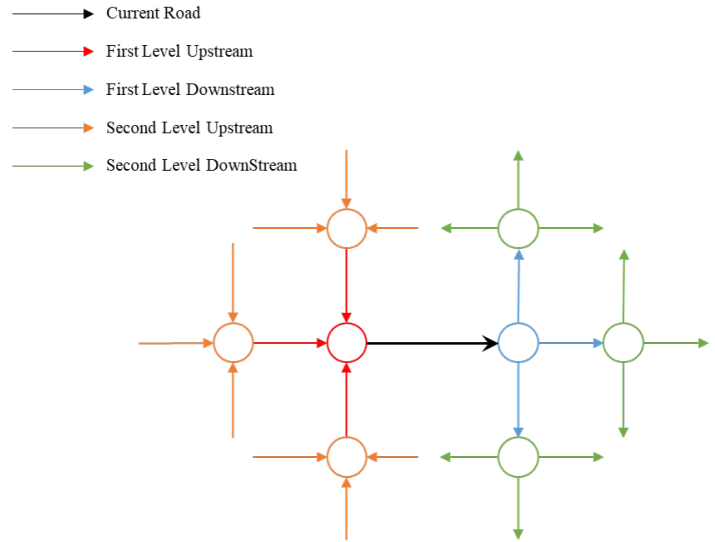

Figure 5: Schematic diagram of the first and second level upstream and downstream roads

As shown in Figure 5, we consider the first and second level upstream and downstream flow data of the current road. However, in the first and second level upstream and downstream roads, it cannot be guaranteed that all the road traffic has a high correlation with the current road flow. The similarity calculation method is used to calculate the similarity of the flow of all relevant roads with the current road, and the roads with weaker correlation are eliminated accordingly. The addition of the flow characteristics of these roads is not conducive to the improvement of the prediction accuracy. This paper proposes to use the weekly average Pearson correlation coefficient to measure the similarity of the flow changes between the current road and the related road. The Pearson correlation coefficient is generally used to analyze the similarity between two ordered vectors of equal length. The equation is as shown in (17):

$$R(X, Y) = \frac{E(XY) - E(X)E(Y)}{\sqrt{E(X^2) - E^2(X)} \sqrt{E(Y^2) - E^2(Y)}} \quad (17)$$

Where E is the mathematical expectation. As the traffic flow changes have a certain periodicity, for example, the weekly traffic changes of a certain road section are similar, as shown in Figure 6:

It shows that a week's traffic flow change can represent the overall traffic flow change of the road section, and the average of the Pearson correlation coefficient of the flow data of a week can be used as the similarity value between the road section and other road sections.

Figure 6: Traffic flows in link 10483 of Wuhan for three weeks

$$R_{week} = \frac{1}{n} \sum_{i=1}^n R_i \quad (18)$$

Then the weekly average correlation coefficient can be expressed as the equation (18), n is the number of days, the value is set to 7, and R_i is the day correlation coefficient. Figure 7 is a flowchart of the overall architecture of NMF-AttLSTM.

3 Experimental and Analysis

3.1 Data Sources

(1) PeMS public data set

The Caltrans Performance Measurement System (PeMS) is a professional traffic flow data collection system. Approximately 15,000 detectors located in major cities in California collect traffic data every day. This paper uses a total of 32 relevant road traffic data from January to March 2017. The traffic data set is counted as 5 minutes, which means that there will be 12 traffic data points per hour. For some missing and abnormal data, the method of moving average is used to fill and correct the abnormal value. In order to obtain the similarity between each road section, a week of data was selected to calculate the weekly average Pearson correlation coefficient, the remaining data was divided into training set and test set, and the effectiveness of the model was evaluated on the test set.

(2) Wuhan City Traffic Data

To verify the prediction effect of the model on the actual road section, the road section 14394 in the core area of Wuhan was selected as the research section, and a total of 30 related road sections in the upstream and downstream were extracted. The relationship between the upstream and downstream is shown in Table 1. Including road traffic data from November to December 2020. The data collection granularity is 5 minutes, which means that 288 data will be collected for each road section every day. Same as the PeMS data set, the abnormal and missing data are also corrected accordingly. And use one week of data to calculate the weekly spatial correlation coefficient, to select high-correlation road sections to extract spatial

features. The actual spatial relationship between section 14394 and its upstream and downstream sections is displayed in QGIS[15] by using OpenStreetMap, as shown in Figure 8.

Table 1: Link number 14394 corresponds to the link number of the upstream and downstream sections

Current Road	Upstream link	Downstream link
14394	14310,14318,14319,	14199,14197,14198,

	14400,14405	

3.2 Experimental Setup

A sliding time window is used to construct a data set of historical data of this road section and its related road sections. The specific process is shown in Figure 9, where S_t represents the characteristic matrix of historical time series data. Assuming that the input sequence length is 10, the prediction lag time is 15 minutes. Since the data is at a granularity of 5 minutes, it moves backward two time units in turn to extract the current road flow as the label. Now the data set is $row_1 : (x_1 : s_1 s_{10}, f_1 : s_{13})$, $row_2 : (x_2 : s_2 s_{11}, f_2 : s_{14})$, By analogy, other data set with different input sequence lengths are constructed.

Due to the many parameters of the proposed prediction framework model, the prediction results are also affected. The important parameters are shown in Table 2. Through related experiments, the most suitable parameters are selected as the benchmark parameters for the experiment.

The model in Figure 9 is used for comparative analysis with the NMF-AttLSTM model.

- SVR[16]: Support Vector Regression (SVR) is a method that uses support vector machines (SVM) to solve regression problems, and is often used for time series forecasting. And use RBF as the kernel function.
- LSTM[6]: Which has good predictive ability for time series problems.
- AE-LSTM[8]: Use AutoEncoder to obtain the characteristics of the upstream and downstream traffic flow data of the internal relationship of the traffic flow, and then use the acquired feature data and historical data to predict through the LSTM network.
- AttLSTM[1]: Use the attention mechanism to extract features, add a layer of AttentionDecoder to the LSTM network, so that the model can extract more valuable information.

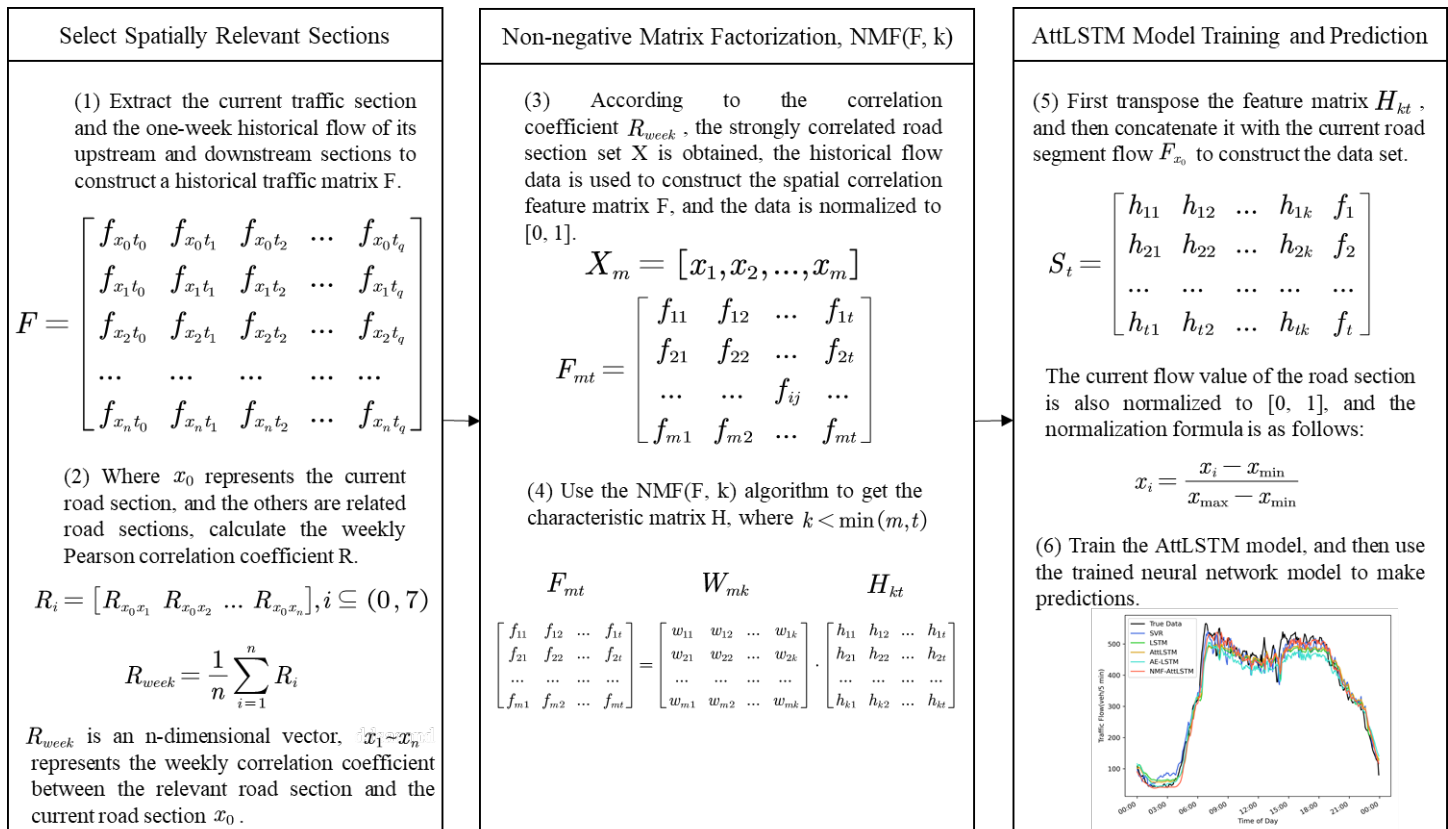

Figure 7: The flow chart of the traffic flow prediction architecture of the NMF-AttLSTM method. The entire prediction process is divided into selection of spatially relevant sections, Non-negative Matrix Factorization (NMF) and AttLSTM model training and prediction. The upstream and downstream sections selected through correlation analysis are used as the input of NMF(F, k), and the feature matrix after dimensionality reduction of the NMF algorithm is spliced with the current section flow as input to predict future traffic flow

Figure 8: Link 14394 and its upstream and downstream sections in Wuhan urban area

As shown in Table 2, we selected about 30 upstream and downstream road sections related to the current road section, and then based on related experiments, determined that the road section with a circumferential spatial correlation coefficient greater than 0.5 would be selected, and the data is reduced by the NMF algorithm.

The size of the parameter k in the NMF algorithm is equal to the dimension of the feature matrix after dimensionality reduction. For the proposed model and the contrasted neural network model, the hyperparameters are set to the same value. The learning rate is 0.001, the optimization algorithm chooses the adam algorithm, and the mean square error (MSE) is used as the loss function.

Figure 9: Constructing a data set through a sliding window

3.3 Model Evaluation

In the experiment, the performance of the traffic flow prediction model is measured by three indicators: Mean Absolute Percentage Error (MAPE), Root Mean Square Error (RMSE) and Mean

Absolute Error (MAE).

$$MAPE(\bar{x}, x) = \frac{1}{N} \sum_{n=1}^N \frac{|\bar{x}_n - x_n|}{x_n} \quad (19)$$

Table 2: Parameters set by default in the experiment

Parameter	Description	Value
n	Number of relevant sections of upstream and downstream	30
R_{week}	Weekly average Pearson correlation coefficient	>0.5
τ	Input time series data length	12,24,36
λ	Learning rate	0.001
	Batch Size	16
	Hidden layer neuron	64
	Prediction interval	15min

$$MAE(\bar{x}, x) = \frac{1}{N} \sum_{n=1}^N |\bar{x}_n - x_n| \quad (20)$$

$$RMSE(\bar{x}, x) = \sqrt{\frac{1}{N} \sum_{n=1}^N (\bar{x}_n - x_n)^2} \quad (21)$$

\bar{x}_n represents the predicted value, x_n represents the observed value, and N represents the number of data. MAPE considers the closeness of the true value to the predicted value and the ratio of the error to the true value, which is often used as a measure of the accuracy of the prediction in the prediction problem. RMSE is used to measure forecast stability. MAE is used to evaluate how close the predicted results are to the real data. The smaller the value, the better the fitting effect.

3.4 Experimental Results

First, use the PeMS public data set for analysis. For different NMF(F, k) algorithm parameters k, under the condition that the input sequence length is 12 and the prediction interval is 15 minutes, the distribution of MAPE is shown in Figure 10. When the parameter k is 5, it has the lowest MAPE error. Here, the parameter k of the NMF algorithm is also equivalent to the reduced dimensionality of the historical data matrix. In subsequent experiments, both the NMF-AttLSTM model and the AE-LSTM model use 5 as the reduced dimension.

We use one day's data to measure the performance of the NMF-AttLSTM model and other comparison models. At the same time, we set three different input sequence data lengths, 12, 24, and 36. They represent the use of 1-hour, 2-hour, and 3-hour historical data as the model input to predict the traffic flow after 15 minutes. Table 3 shows the performance of each model at different input sequence lengths. The results show that as the input sequence length increases, the MAPE, MAE, and RMSE of the AttLSTM model and NMF-AttLSTM model decrease, which proves that the model with the attention mechanism is more advantageous than other models when

the length of the input sequence increases, because the model with the attention mechanism can extract more important features from the long sequence input. Under the same input sequence length, the NMF-AttLSTM model and the AE-LSTM model have better performance than other models. Due to the addition of upstream and downstream related road section features, the model provides the characteristics of traffic flow changes. In all the experimental results, the proposed NMF-AttLSTM model has the lowest MAPE, which proves that the model can not only use the spatial characteristics of traffic flow changes, but also obtain more important features from historical flow data, enhancing the prediction ability of neural network model for traffic flow.

Figure 10: MPAE error of NMF-AttLSTM model under different dimensionality reduction parameter k (PeMS)

Table 3: Performance comparison of models under different input sequence lengths (PeMS)

Input Length	Model	Error Value		
		MAPE(%)	MAE	RMSE
12	SVR	12.43	24.00	30.96
	LSTM	12.52	27.68	35.65
	AttLSTM	10.96	26.02	34.92
	AE-LSTM	12.15	36.65	46.96
	NMF-AttLSTM	9.10	22.72	31.49
24	SVR	12.23	24.31	32.85
	LSTM	13.20	25.32	31.88
	AttLSTM	10.50	26.30	34.57
	AE-LSTM	8.60	22.23	30.41
	NMF-AttLSTM	8.48	21.46	29.27
36	SVR	12.91	29.28	37.59
	LSTM	11.53	25.84	33.45
	AttLSTM	9.07	24.61	32.54
	AE-LSTM	9.29	22.45	30.08
	NMF-AttLSTM	7.89	15.21	19.92

In order to verify the effectiveness of the proposed model on the actual road section, the road section 14394 in the core area of

Wuhan is selected for analysis. The specific location is shown in Figure 7. According to the method proposed in Section 2.3, firstly, the correlation between each upstream-downstream road section and the current road section is calculated by using the weekly spatial correlation coefficient. Finally, the correlation coefficients of the upstream and downstream sections with a correlation greater than 0.5 with 14394 are obtained, as shown in Table 4. Among the 30 upstream and downstream road sections, 14 relevant road sections are selected. The historical flow data of these 14 relevant road sections are used to construct the historical data matrix F , and then the NMF algorithm is used to obtain the traffic flow spatial characteristics H . For the NMF(F, k) algorithm, the effect of different k on the results was also tested. As shown in Figure 11, the results show that k is 7 with the lowest MAPE.

Table 4: Weekly spatial correlation coefficients of relevant sections in the upstream and downstream of road section 14394 of Wuhan

Upstream		Downstream	
Link ID	Correlation coefficient	Link ID	Correlation coefficient
14310	0.805	14198	0.639
14322	0.805	14200	0.942
14392	0.811	14317	0.941
14742	0.496	14315	0.941
14400	0.660	14316	0.936
14405	0.593	14222	0.638
		14223	0.926
		14195	0.634

Figure 11: MPAE error of NMF-AttLSTM model under different dimensionality reduction parameter k (Wuhan)

For road section 14394, also use one day's data to predict the performance of the model. In the experiment, the input sequence length is 12 and the prediction interval is 15 minutes. Table 5 shows the prediction errors of different models. The results show that the proposed NMF-AttLSTM model has the lowest MAPE. However, because road section 14394 of Wuhan and its upstream and down-

stream sections are all branch sections, compared with PeMS, the flow value is generally low, so its MAPE error is higher, MAE and RMSE error are lower.

Table 5: Performance comparison of each model (Wuhan)

Model	Error Value		
	MAPE(%)	MAE	RMSE
SVR	22.92	3.27	4.39
LSTM	20.40	3.35	4.75
AttLSTM	18.35	3.29	4.75
AE-LSTM	18.75	3.16	4.22
NMF-AttLSTM	16.54	3.01	4.13

Table 6: Performance comparison of each model under two data sets

Data Set	Model	Error Value		
		MAPE(%)	MAE	RMSE
PeMS	SVR	12.52	25.86	33.80
	LSTM	12.41	26.28	33.66
	AttLSTM	10.17	25.64	34.01
	AE-LSTM	10.01	27.11	35.81
	NMF-AttLSTM	8.49	19.79	26.89
Wuhan	SVR	22.92	3.27	4.39
	LSTM	20.40	3.35	4.75
	AttLSTM	18.35	3.29	4.75
	AE-LSTM	18.75	3.16	4.22
	NMF-AttLSTM	16.54	3.01	4.13

Figure 12: The prediction result of each model under the condition that the input sequence length is 12 (PeMS)

Figure 13: The prediction result of each model under the condition that the input sequence length is 12 (Wuhan)

Figure 14: Comparison of MAPE errors of different models in PeMS and wuhan datasets

Table 6 shows the comparison results of the PeMS data set and the wuhan data set. Under the condition that the prediction interval is 15 minutes, the experimental results of the PeMS data set show that the MAPE of the NMF-AttLSTM model is reduced by 1.68% compared with the AttLSTM model and 1.52% compared with the AE-LSTM model. The experimental results of the wuhan data set show that the MAPE of the NMF-AttLSTM model is reduced by 1.81% compared with the AttLSTM model and 2.21% compared with the AE-LSTM model. As shown in Figure 14, NMF-AttLSTM has the lowest MAPE error on both data sets. The results on different experimental data sets prove the effectiveness of the proposed NMF-AttLSTM model.

Figure 12 and Figure 13 respectively describe the results of using one day's data prediction on the PeMS and Wuhan datasets. It can be seen that the results of the proposed NMF-AttLSTM model fit better with the true values. Figure 15 is the cumulative distribu-

tion function (CDF) diagram of the MAE error of the prediction results of each model. CDF can describe the probability distribution of the MAE error. The result shows that the MAE error of NMF-AttLSTM on PeMS is less than 20, accounting for more than 60%. The MAE error on the Wuhan dataset is less than 5, accounting for more than 80%, which is better than other models.

(b) Wuhan

Figure 15: The CDF of MAE error for different models of PeMS and Wuhan data sets

4 Conclusions

The paper studies the method of using the temporal and spatial characteristics of traffic flow to predict traffic flow, and proposes a short-term traffic flow prediction framework based on the NMF-AttLSTM model. First, analyze the correlation between each upstream and downstream road section and the current research road section by using the weekly spatial correlation coefficient, and eliminate the road sections with low correlation. Then use the NMF algorithm to extract the features of the selected road sections, and finally combine the extracted features with the historical traffic information of the current road section, and use the AttLSTM model for training and prediction. The algorithm considers the spatial relationship of traffic flow, effectively utilizes the flow information of upstream and downstream sections, and also reduces the dimension of data.

In addition, an attention mechanism is added to the LSTM model, so that the LSTM model can extract more valuable features from historical data. This research only considers the relevant flow information of the upstream and downstream sections. In the subsequent work, we can consider adding more complex road network topology information to improve the performance of the model.

ABSTRACT

This paper examines the impacts of the COVID-19 pandemic and selected commodity variables on Booking.com share price using the Markov-switching approach. Daily data spans from January 2017 through July 2020 are utilized in this study. Empirical evidence showed that COVID-19, international crude oil price, and gold price affected the Booking.com share price significantly. A positive relationship was detected between international crude oil price and gold price towards stock price whereas COVID-19 showed an inverse impact on stock price. The empirical findings evidenced a 1% increase in COVID-19 cases adversely affecting the share price by -0.27%. Our findings also suggested that the potential of another wave of COVID-19 is relatively higher as the bounce back period was identified as 67 days. The filtered and smoothed probabilities signaled the Booking.com share price chronologically, and transition probabilities were identified. Six cycles were outlined, and the effectiveness of the Markov-switching approach in detecting vulnerable financial forecasting was demonstrated. The adequate dating evolution provided satisfactory input for policymakers, investors, and researchers to design and mitigate volatility in commodities and crises.

1. Introduction

COVID-19 was declared as a Public Health Emergency of International Concern by the World Health Organization (WHO) at the end of January 2020. It is now well established that COVID-19 has greatly impaired the world economy, especially the tourism industry, with airplanes grounded, hotels closed, and restrictions placed on travel around the world. The World Tourism Organization (UNWTO) stated that the pandemic has placed the whole world on lockdown, and most destinations worldwide are still implementing COVID-19 related travel restrictions on international tourists. In [1], the author documented a double-digit (-22%) decline in international tourists in 2020Q1, with 57% reduction in arrivals in March, which is equivalent to a total loss of 67 million international tourists and USD80 billion in tourism export revenues. The UNWTO foresees a total decline of 58% to 78% in international tourist arrivals in the year 2020, and a total of 100 to 120 million tourism jobs are directly at risk in the current scenario. This is by far the worst outcome since 1950 in the history of international tourism, a circumstance that will bring an abrupt end to a 10-year stretch of continuous growth following the financial crisis of 2009.

Due to the fast spread of the COVID-19 pandemic, most countries are responding quickly and effectively through international cooperation, particularly in terms of healthcare systems and financial support to protect people against the loss of their livelihoods. This step has moved closely to achieve several Sustainable Development Goals (SDGs), which are good health and well-being (Goal 3) and partnerships for the goals (Goal 17). Scientists around the world are working on potential treatments and vaccines to reduce the number of people infected and the number of deaths due to the pandemic and its related effects. Due to the outbreak of COVID-19, the UNWTO foresees the tourism industry facing an unprecedented challenge. The UNWTO accordingly hosted a virtual high-level meeting with key UN agencies, member states, and the private sector to work together as the Global Tourism Crisis Committee in responding to the emerging situation and to ensure that tourism is ready to lead recovery efforts.

Along with the rapid development of the tourism sector, the hospitality industry is one of the key pillars in receiving and serving tourists. Hotels are considered pivotal tourist facilities as one of the drivers of investment and employment in tourism [2]. Currently, the hospitality industry is facing an unprecedented challenge due to the worldwide lockdowns put in place by various countries. Booking.com is one of the world's leading digital travel

<https://dx.doi.org/10.25046/aj060221>

platforms, operating on numerous well-known online platforms such as Agoda, Villas, and Kayak. With its significant contribution and diversify profile, the Booking.com share price was chosen for this study. Figure 1 reveals that the share price of Booking.com is sensitive not only to economic crises (dot-com bubble and subprime mortgage crisis) but also health crises (SARS outbreak and H1N1). These incidents have previously disrupted the travel industry, limiting the ability and willingness of tourists to travel to certain destinations, which result in a decline in demand that affects the travel industry as a whole. Due to the COVID-19 pandemic, the total revenue for Booking.com was USD2.3 billion in the first quarter of 2020, a decline of 19% from the preceding year. Furthermore, net cancellations were USD12.4 billion, marking a 50% increase from over a year ago [3]. Thus, very little is known about the impact of COVID-19 on hotel stock returns. In addition, the oil price slump has contributed further to stock volatility. The sharp decline in oil price is mainly due to agreements between OPEC+ members to reduce oil production and the fact that global demand for crude oil has declined dramatically due to the COVID-19 pandemic. In short, the stock market faces dual shocks from the COVID-19 pandemic and oil price changes. With respect to these issues, this study has two primary aims: first, to investigate the impact of COVID-19 on hotel stock market performance; second, to ascertain the impact of commodity price volatility on the hotel stock market.

2. Literature Review

The COVID-19 pandemic has had a tremendous impact on the world economy and has put millions of people as well as jobs at risk. Tourism is among the hardest-hit industries during the pandemic. The hotel industry is one of the most highly interlinked industries in tourism, and almost every part of a hotel's operations from room occupancy rate, staffing plan, and stock price have been affected by COVID-19. The stock market is an interesting topic that has prompted many empirical studies to be carried out from economic and financial perspectives. However, the health crisis has only recently become a topic of interest, and the impact of COVID-19 has not yet been widely analyzed. Additionally, the effect of COVID-19 on international tourism is extremely challenging to estimate, considering the unparalleled and rapidly changing complex nature of the crisis. Thus, the current study will enrich the literature by examining the impact of COVID-19 on the tourism stock market. In previous studies, [4] explored the impact

of macroeconomic variables, terrorist attacks, and natural disasters on hotel stock returns. The researchers also pointed out that the SARS outbreak caused a decline in hotel stock returns recorded at an approximate value of -25.9%, followed by the impactful declines resulting from earthquake (-22.3%) and the 9-11 terrorist attacks (-12.5%). Similarly, [5] analyzed the effect of SARS on fluctuations in Taiwanese hotel stock prices. They also identified that the tourism industry experienced the highest decline in overall stock prices in the Taiwanese Stock Exchange, recording a decline of approximately 28.9% one month after the SARS outbreak. They indicated that the average hotel stock prices were exposed to above-market risk during the SARS outbreak.

International crude oil price fluctuations have substantial effects on different areas of the financial sector, especially the stock market. In [6], the author investigated the relationship between oil price and performance of the US stock market, identifying a clear adverse link between oil price and stock market performance. Similarly, [7-10] also found evidence of an adverse connection between oil price and stock price. In contrast, [11-13] detected a positive relationship between the oil price and the stock price. In [14], the author stated that oil-exporting countries were positively associated with the stock market, whereas the adverse impact occurred in oil-importing countries. Other key determinants such as gold [15, 16], GDP [17, 18], exchange rate [16, 18-19], and economic crises [10, 20-22] were employed in previous studies.

3. Methodology

Instead of using the traditional single-state approach, Markov-switching regression techniques that confirm the validity of crises were applied in this study. A similar approach was applied in different tourism issues by [23-25] with constructive findings. The current study tends to establish the links among different crises and tourism demand forecasting, with tourism stock price as the proxy variable. In examining the behavior of the commodity market towards world tourism performance together with the health crisis, inclusive of COVID-19 as the dummy variable into the regression, remedial measures or precautionary steps can be tackled cautiously for the next crisis occurrence. All the variables were extracted in the high frequency on a daily basis from January 2017 to July 2020 to capture the most recent information. The selected variables comprise the share price of Booking.com as a proxy for world tourism, and the commodity variables are international crude oil price and gold price. Table 1 displays the descriptive statistics of the selected indicators.

Table 1: Descriptive Statistics of the Selected Indicators

	LBOOKING	LBRENT	LGOLD
Mean	7.514	4.056	7.209
Median	7.530	4.127	7.168
Maximum	7.699	4.454	7.924
Minimum	7.049	2.197	7.048
Standard Deviation	0.105	0.291	0.109
Skewness	-1.257	-2.377	1.264
Kurtosis	5.410	10.280	4.786

According to [26], the general definition of the piecewise linear switching regression model is as follows:

$$y_t = \sum_{j=1}^r (\phi'_j q_t + \varepsilon_{jt}) I(c_{j-1} < s_t \leq c_j) \quad (1)$$

where $q_t = (w'_t = y_{t-1}, \dots, y_{t-p}; x'_t = x_{1t}, \dots, x_{kt})$ denotes the explanatory variables and observable switch variable [27] interpreted the scheme of switching regression as follows:

$$y_t = \begin{cases} \beta_1 \cdot x_t + \varepsilon_t, & \text{when } S_t = 1 \\ \beta_2 \cdot x_t + \varepsilon_t, & \text{when } S_t = 2 \end{cases} \quad (2)$$

where the exogenous regressors are represented by y_t and x_t , the vector of real numbers is denoted by β_t , the non-observable state variables are shown by S_t , and the Gaussian white noise by ε_t .

The Markov-switching regression model is presented in the following section. The COVID-19 pandemic is captured by a dummy variable with the outbreak detected at the end of 2019.

$$\text{Booking}_{i,t} = \begin{cases} \beta_0^{(1)} + \beta_{Brent,t}^{(1)} + \beta_{Gold,t}^{(1)} + \text{Dum}_{COVID-19,t}^{(1)} + \varepsilon_t^{(1)} & S_t = 1 \\ \beta_0^{(2)} + \beta_{Brent,t}^{(2)} + \beta_{Gold,t}^{(2)} + \text{Dum}_{COVID-19,t}^{(2)} + \varepsilon_t^{(2)} & S_t = 2 \end{cases} \quad (3)$$

Upon the coefficient determination, the transition probabilities of the regression model were presented to examine the timeframe of the tourism cycle moving from one regime to another. The longer timeframe indicates that a recession might take a longer time to recover from a crisis. The matrix of transition probabilities from one state to another state is presented below:

$$\pi = \begin{bmatrix} p_{11} & p_{21} \\ p_{12} & p_{22} \end{bmatrix}, p_{xy} = \text{Prob}(S_t = y | S_{t-1} = x) \quad (4)$$

Furthermore, the smoothed and filtered probabilities where $\text{Prob}(S_t = y | y_1, \dots, y_T)$ can be obtained as well. The graphical illustration of the world tourism cycle detected the reference chronology of crises happening from 2017 to 2020 worldwide. Moreover, the empirical results underwent a series of diagnostic checks for the residuals. The best fit of the model can be determined by the residual diagnostic tests, which include the plot of residuals against a fitted value and the normality probabilities plot for normality distribution testing. Further research can also apply a similar approach to different fields of study.

4. Results and Discussion

Hotels play a vital role in the tourism industry and have been categorized as one of the most vulnerable industries during the COVID-19 pandemic. This section discusses the impact of the COVID-19 pandemic and commodity variables on hotel stock price (Booking.com) through a Markov-switching approach. Table 2 reveals that international crude oil price, gold price, and the COVID-19 pandemic significantly affected the share price of Booking.com in both regimes. In regime 1, the international crude oil price and gold price are positively associated with the share price of Booking.com, while the COVID-19 pandemic adversely affected the share price. Oil is one of the most tradeable commodities, and a crash in oil price reflects fear of economic recession. The world economy, including oil-producing countries such as the US, Saudi Arabia, and Iran, has been disrupted due to the COVID-19 pandemic. In addition, the pandemic is also having huge impacts on the tourism industry, manufacturing industry, and factories that consume a large portion of energy in production but

have been shut down. Thus, the demand for crude oil has dropped dramatically. Our empirical results show that oil price and stock price move in the same direction. A 1% decline in oil price weakened the share price of Booking.com by 0.20% during the COVID-19 pandemic in regime 1, as shown in Table 2.

Table 2: Markov Switching Model Results

Regime 1: Recession		
Variable	Coefficient	p-value
(Intercept)	3.142	0.000***
LBRENT	0.200	0.000***
LGOLD	0.504	0.000***
COVID-19	-0.268	0.000***
<i>R-squared</i>	0.855	
Regime 2: Expansion		
Variable	Coefficient	p-value
(Intercept)	0.582	0.000***
LBRENT	0.345	0.000***
LGOLD	0.762	0.000***
COVID-19	-0.020	0.000***
<i>R-squared</i>	0.847	

Gold acts as a good diversifier and is categorized as a Safe Haven, which is beneficial to investors [28]. Hence, investors feel even more confident when the gold price increases and leads to a rise in stock price. In this study, the results show that gold price is positively associated with stock price, which is consistent with the findings of [15-16]. In regime 1, a percent increase in gold price will lead the share price of Booking.com to rise by 0.50%. As expected, the COVID-19 pandemic had a negative impact on the hotel's stock performance. The results demonstrate that a percent rise in COVID-19 cases will lead to Booking.com's share price to be reduced by 0.27% during the recession. This negative relationship also implies that tourists feel a high risk to travel because safety is a fundamental condition for international tourists. The values of the adjusted R^2 are higher than 80% in both regimes, signifying that the variability of the dependent variables can be explained accordingly by the selected explanatory variables.

Table 3: Matrix Transition Probabilities

	Regime 1	Regime 2	Duration (days)	P
Regime 1	0.985	0.015	67	$\begin{bmatrix} 0.985 & 0.015 \\ 0.015 & 0.985 \end{bmatrix}$
Regime 2	0.015	0.985	67	

Figure 2. Graphical Illustrations of Smoothed and Filtered Probabilities

Table 3 demonstrates the two-state transition of matrix transition probabilities. The measurement of the expected duration for the regime-switching period is defined as $1/(1-P_{00})$, in which the higher transition probability value reveals that it is relatively more difficult to shift from one regime to another. Findings reveal that the model shows 98.5% to stay in regime 1, and only with a 1.5% probability of shifting to regime 2. Therefore, the expected duration to shift from regime 1 to regime 2 is 67 days during the COVID-19 pandemic. The shorter expected duration results from the matrix transition probabilities illustrates that the potential of another wave of COVID-19 is relatively higher, as the bounce back effect shown in Table 3 is stronger. This may be due to resumed domestic and international economic activities and lifted restrictions on travel and activities.

Figure 3. Diagnostic Checking Analysis Outcome

The graphical illustrations of the smoothed and filtered probabilities from the Markov-switching regime model are depicted in Figure 2. A total of six states/shaded areas for the crises were detected, spanning from January 2017 to July 2020. The argument on oil production cutting among oil-producing countries that started in 2017 is well captured in the first shaded area, as illustrated in Figure 2. The second state captured the worst point drop in the history of the Dow Jones in February 2018. In addition, US markets lost nearly USD2 trillion in October 2018, which is identified in the third shaded area, and the fear of US-China trade tension continued in February 2019 and November 2019. Finally, the COVID-19 pandemic is successfully captured in the sixth shaded area. This proves the effectiveness of the Markov-switching approach in detecting economic crises. Figure 3 illustrates that the residuals are considerably fitted against the values. Following the normal Q-Q plot closely, the residuals are like white noise and are moving towards the normal distribution.

5. Conclusion and Policy Recommendation

This paper examines the impact of the COVID-19 pandemic on share price of Booking.com through the Markov-switching approach. The empirical findings reveal that the highly contagious disease had negatively influenced hotel stock market performance. Furthermore, a positive associated relationship was identified among international crude oil price, gold price, and stock price. The results also provide strong evidence that the model stays persistent within each regime up to more than 90%. Several economic crises have been captured through smoothed and filtered probabilities under this study. Our findings have several implications. First, they contribute to the current literature regarding the impact of the COVID-19 pandemic on hotel stock performance. Second, the investors have a better understanding of the dynamic relationship between the commodity variables and stock market. Specifically, they are able to adopt more appropriate strategies to safeguard against oil and gold price fluctuations and future crises. Finally, the findings are helpful in providing the government and policymakers with useful insights about the impact of crisis on the stock market, and thus to design a feasible policy to protect the country and society. Further research is needed to fully understand the implications of COVID-19 on the stock market. This would be a fruitful area for further work by taking into account the impact of COVID-19 across different industries. Additionally, future work can utilize different elements and methodologies to gather extra information regarding COVID-19's impact on tourism-related industries.

ABSTRACT

The control of the air-fuel ratio (AFR) is critical for the efficiency of the combustion. This is for achieving the better performance of the plant and result in high output energy. Computation of the AFR is gone considering the composition of the fuel regardless of the inlet pressure, density and temperature of both fuel and the air. This paper models AFR as a function of the inlet temperature, density, and pressure. Formulated models have been checked using recorded data from the Jabana2 Oil Power Plant. The results show that the AFR increases by 1.5 units as the pressures of the gas increase by 0.6 bars but when it reaches 2.9 bar, AFR starts to decrease, 0.9% of the increase of the density leads to the decrease of the AFR of 0.4 in average. 3.5°C rise of inlet temperature lift the AFR by 0.2; however, it starts to decrease when the temperature reaches 78°C.

1. Introduction

The combustion within the boiler burns fuel to create heat energy. The burning of fuel is the reaction of fuel with oxygen present in the air. The amount of fuel that can be burnt is limited by the quantity of oxygen [1]. Once all the fuel is not burnt at all, some of it stays in the boiler and other quantity goes into the atmosphere as flue gases [2]. This is the loss that causes small efficiency at some time abuses our environment [3]. It is therefore important to maintain AFR at optimum.

By definition, AFR is the fraction of air mass and the fuel mass. Different research like [4] and [5] among others, have been conducted considering the quantification of the air composition and the fuel composition. In [6], the author quantified these masses for complete combustion and also formulated the heating capacity based on the composition of the fuel. This is very important however other physical variables can alter the behavior of the AFR.

In [7], the author examined the role of variation of temperature inlet for lean air/fuel and designed the cylinder

porous burner which absorbs the heat of combustion for a lean mixture of propane. They found that adjusting the flow rate of both air and propane gives high power output and efficiency when working at a normal temperature. This means that since the fuel is found at a different temperature, there is a need of knowing at which temperature is to be inserted, which affects also the density and pressure.

In [8]-[12], the researchers have all searched on the contribution of the temperature, the density, and the pressure and found that there are their influences on the combustion as well as the AFR. However, they didn't estimate the how much they contribute. It is important to know how much any of its change varies the AFR at any kind of the fuel to achieve better combustion for efficient boiler performance.

In [13], the author found that the rich fuel in combustion leads to the formation of the thick porous zone which is one of the sources of the flame with exothermic chemical transformation. This is the cause of higher exhausts and therefore the fuel entry is to be managed.

These researchers demonstrated how the air-fuel ratio should be based on physical properties. However, on the field, the air-fuel ratio is calculated based on the composition of the fuel to be burned as regarded in these references among others [14]-[17].

In this research work, the AFR is modeled as a function of the inlet temperature of the fuel and the outlet density of the gases, then as a function of the pressure at the entry of the air.

Section 2, demonstrate the model of the AFR with the variation of the density and the temperature and validate it using experimental data from the field. In section 3, the author demonstrates the model of the AFR with the change of the pressure, and experimental results are presented. In section 4 there is a conclusion, recommendations as well as proposed for future work.

Nomenclature

(t): Internal energy, \dot{H} : Enthalpy

$\dot{Q}(t)$: Heat Q_f : Heat transfer by radiation

Q_L : Heat transfer by furnace wall

LHV : The lower heating value of the fuel

\dot{m}_f : Fuel mass flow rate, \dot{m}_{fb} : Burned fuel mass flow rate

V_f : Furnace volume, ρ : Density, t_c : Combustion period

t_{cmax} : Maximum combustion period, r : Constant of the perfect gas

V : Volume, T : Temperature, M : Mass

P : Pressure, μ : Molecular mass

q_a : Airflow, q_{O_2} : Oxygen flow

q_{N_2} : Nitrogen flow, m_{O_2} : A mixture of oxygen (%)

m_{N_2} : A mixture of nitrogen (%)

Subscripts: c :coal/fuel, e :Exhausts

2. Consideration of the Density and the Temperature

The AFR is modeled by the quotient of the model of the air and fuel [18]. To do that let consider the entry and exit of the particles within the boiler and utilize the principle of energy and mass conservation. Analysis of the mass entry and exit in the furnace in Figure 1 helps for that analysis.

2.1. Model formulation

Figure 1 shows that the inputs which vary with time are the fuel and the air. The output is gas pressure. The general form of mass conservation stated by the law of thermodynamics [19], [20] says that under the assumption that there is no heat and mass

transfer in the walls as well as a change in kinetic and potential energies during the flow.

Figure 1: Entry and Exit of the furnace

$$\frac{d}{dt} m(t) = \dot{m}_{in}(t) - \dot{m}_{out}(t) \quad (1)$$

$$\frac{d}{dt} U(t) = \dot{H}_{in}(t) - \dot{H}_{out}(t) + \dot{Q}(t)$$

Considering or both energy and mass, we can have the following equations [21], :

$$V_f \left(\frac{d(\rho_g \cdot h_g)}{dt} \right) = \dot{m}_a h_a + \dot{m}_{fb} LHV - \dot{m}_g h_g - Q_f - Q_L \quad (2)$$

$$\dot{m}_{fb} = \dot{m}_f (1 - e^{-\frac{t_{cmax}}{t_c}}) \quad (3)$$

With the conservation of mass, this is the equation resulting from equation (1)

$$V_f \frac{d\rho_g}{dt} = \dot{m}_a + \dot{m}_{fb} - \dot{m}_g$$

$$\dot{m}_a = V_f \frac{d\rho_g}{dt} - \dot{m}_{fb} - \dot{m}_g \quad (4)$$

Inserting (3) in (4) yields

$$\dot{m}_a = V_f \frac{d\rho_g}{dt} - \dot{m}_f (1 - e^{-\frac{t_{cmax}}{t_c}}) - \dot{m}_g$$

$$\frac{\dot{m}_a}{\dot{m}_f} = \frac{V_f}{\dot{m}_f} \frac{d\rho_g}{dt} - (1 - e^{-\frac{t_{cmax}}{t_c}}) - \frac{\dot{m}_g}{\dot{m}_f}$$

$$AFR = \frac{V_f}{\dot{m}_f} \frac{d\rho_g}{dt} - (1 - e^{-\frac{t_{cmax}}{t_c}}) - \frac{\dot{m}_g}{\dot{m}_f} \quad (5)$$

Equation (3) shows that maximum mass burned, (m_{fb} tends to m_f), if combustion period t_c tends to maximum combustion t_{cmax} .

2.2. Analysis of the data collected from the site

The model is to be validated by comparing measure values with computed using equation (5); doing that for different plants. Data from Jabana II Oil Thermal Power Plant have been used. The density of the gas and the temperature of the fuel at unlet have been used to compute the Air Fuel Ratio keeping all other parameters in equation (5) constant. $\frac{V_f}{\dot{m}_f}$ which is the inverse of the density of the fuel at the beginning is kept to $2m^3/kg$, $T_f = 30^\circ C$ and τ close to $T_f = 23$.

The results are shown in the figures.

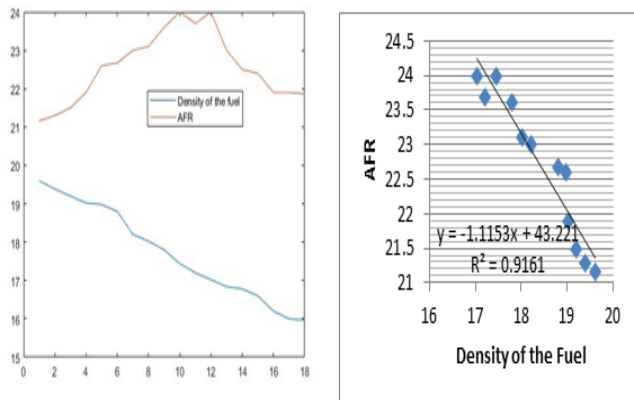

Figure 2: Variation of the Air Fuel Ratio and the Density of the Fuel

Figure 3: Variation of the Air Fuel Ratio with the temperature of the fuel

Figure 1 shows how the AFR is inversely proportional to the density and Figure 3 shows that the increase of the temperature would lead to the increase of the AFR, however, this change has a limit for both the density and the temperature.

Figure 4: Comparison of measured and Calculated AFR

3. Consideration of the Pressure

This is based on the physical principle of conservation of momentum and mass variation of the pressure, proportional to the mass variation as stated in [20] assuming that the pressure in the furnace is equal to the atmospheric pressure.

$$\frac{dP}{dt} = \frac{r}{V} \cdot T \cdot \frac{1}{\mu} \cdot \frac{dM}{dt} \quad (6)$$

Under an assumption that the internal pressure of the furnace is close to the atmospheric pressure i.e. case of perfect/ideal gasses).

$\begin{cases} q_{O_2} = m_{O_2} q_a \\ q_{N_2} = m_{N_2} q_a \end{cases}$, m_{O_2} : the mixture of oxygen and m_{N_2} : the mixture of nitrogen.

The quantity of the oxygen and nitrogen flow with time depends also on the percentage in the air; so

$$\frac{1}{\mu} \frac{dM}{dt} = k_a q_a \text{ for } k_a = \frac{m_{O_2}}{\mu_{O_2}} + \frac{m_{N_2}}{\mu_{N_2}}$$

On another hand, the coal or fuel flow in use consists of a mixture of carbon, hydrogen, sulfur, nitrogen, and oxygen (from water vapor) in different percentages. The combustion of each of the element of the air produces CO_2 , H_2O , SO_2 , and NO_2 [21]. For the case of Oxygen, it is negative, since it is present in the air but it doesn't undergo the combustion process.

This yields the following

$$\frac{1}{\mu} \frac{dM}{dt} = k_c q_c \text{ for } k_c = \frac{m_{CO_2}}{\mu_{CO_2}} + \frac{m_{NO_2}}{\mu_{NO_2}} + \frac{m_{SO_2}}{\mu_{SO_2}} + \frac{m_{H_2O}}{\mu_{H_2O}} - \frac{m_{O_2}}{\mu_{O_2}}$$

Using the variation of total mass within the furnace by the fact that both air and the fuel enter but the exhaust q_e exit, the following expression will result.

$$\frac{1}{\mu} \frac{dM}{dt} = k_c q_c + k_a q_a - k_e q_e \quad (7)$$

A combination of (6) and (7) gives

$$\begin{aligned} \frac{dP}{dt} &= \frac{r}{V} T (k_c q_c + k_a q_a - k_e q_e) \\ \frac{1}{q_c} \frac{dP}{dt} &= \frac{r}{V} T \left(k_c + k_a AFR - k_e \frac{q_e}{q_c} \right) \\ \frac{1}{q_c} \frac{dP}{dt} &= k AFR + k k_c - k k_e \frac{q_e}{q_c} \text{ for } k = \frac{r}{V} T \end{aligned}$$

Finally, the resulting model is found as follows.

$$AFR = \frac{1}{k C_c} \frac{dP}{dt} + k_c - k_e \frac{q_e}{q_c} \quad (8)$$

3.2. The use of the data from the site/Jabana2 Oil Power Plants

Jabana 2 Oil Power plant is the fossil fuel energy source operating in Rwanda since 2009, producing 20MW of the power Owned by Rwanda Energy Group. It used Heavy Fuel Oil (HFO). At Jabana 2, HFO is pre-heated from 15C for achieving good viscosity. Its density is not controlled and the unlet air temperature is not changed from the ambient value. However, these values at the inlet aren't controlled, their operation data show that they change the overall efficiency of the plant and the quantity of the exhausts.

Figure 5: Variation of the Air Fuel Ratio with the pressure of the fuel

Figure 5 shows that the increase of the pressure and the temperature causes an increase in the air-fuel ratio but it starts to decrease when the pressure becomes higher.

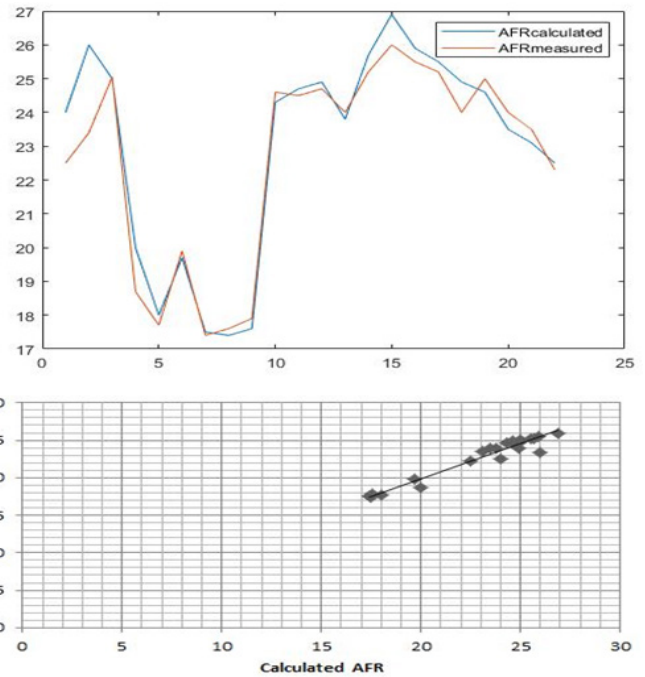

Figure 6: Comparison of Measured and Calculated AFR

Figure 6 shows that values found by calculating using the demonstrated equation (8) and the value of the AFR measured are close.

4. Conclusions

The increase of the temperature and reduction of the density of the air make the AFR high before it reaches the values at which it starts to reduce. Since the quantity of the fuel depends on how much energy is to be produced, the AFR is mainly altered by altering the quantity of the air. As the results show, this quantity of the air would be increased proportionally to the air temperature but when the temperature reaches 80C, the air is to be reduced as shown in Figure 3. About the pressure, it is visible from Figure 5 that from 3bar the air is to be increased within the burner but when arrived to 8bar, the quantity of the air is to be reduced for better combustion. For the case of the density, it is advantage to the AFR to have small density according to Figure 2, but if it continues to reduce up to 8kg/m², the air should be reducing. These considerations are advantages in the sense that all the fuel will be burned without remaining air which contain nitrogen to form nitrite exhausts. The variation of the density, pressure, and temperature could be done to meet the AFR that has to be achieved. Besides harvesting more energy, this is important for minimizing environmental pollution as it reduces exhaust gases.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors acknowledge the facilitation of Jabana 2 Oil Power plant to do experiment in the industry.

ABSTRACT

Artificial Intelligence (AI) is a promising trend in ship energy management systems (EMS). The motivations of this work are designing and implementation of an intelligent energy management system for ship's electric power system based on an adaptive Neuro-Fuzzy Inference System (ANFIS) and the ship power source is an environmental friend system consists of proton exchange membrane fuel-cell (FCPM) considered as the main power source and battery bank as an electric storage system using (ANFIS) to manage the fuel cell generation by solving the optimization problem to reduce the Hydrogen fuel consumption and ensure the system balance. The benefit of using this technique is to penetrate a new field of using renewable and sustainable energy sources in marine to reduce greenhouse emission and increase the sailing period, system reliability by interfacing with the ship's integrated power system. The simulation of this system is carried out by MATLAB® software and (EMS) is implemented to test rig hardware with computer and interface card to emulate the ship's electric power system. The results obtained from the simulation are compared with the experimental results for the evaluation of the EMS performance.

1. Introduction

Traditional marine power plants mainly are intended to move fossil fuel and gas turbine, which is the major source of NOx and the dominant sources of total hydrocarbons (THCs) from Cox and Particulate Matters, causing air pollution [1], and reducing the ship's running costs [2]. Researchers recently started to analyze the air quality in the Pearl because of the current emissions of ships [3], to analyze the characteristics of ship emissions [4], and to analyze the effects of air pollution emissions from the ship [5]. To substitute fossil fuel, renewable energy solar and wind power, fuel cells, and hydrogen, clean-fuel options such as Liquefied natural gas (LNG), methanol, and ethanol should be proposed [6]. Ship power plant applications should be proposed.

Clean energy will achieve the target for saving energy and reducing the ship's emission however using a single energy source is not a satisfactory solution because it is affected by meteorological conditions that are not constant [7]. The restriction

from the International Maritime Organization (IMO) to control the greenhouse gas emission from the ships allows using renewable energy in a wide range [8]. So the shipbuilders began to take the trend of zero-emission ships [9].

Also, using autonomous ships that can sail for a long time without refueling[10]. Renewable energy provides the ship's electrical power with high-efficiency power, less noise, and near-zero-emissions than the conventionally used fossil fuel [11].

Going toward green ships became obligatory conditions, All-Electric Ship (AES) technique which moving toward replacing the ship's power system, with electric power sources [12] with the clean, safe, cheap and, smart sources that are renewable energy sources such as solar, wind and fuel-cell systems [13], [14]. The broader areas of ports suffered from pollution by shipboard emissions when berthing so the U.S. Navy initiate European project EL-EMED namely the introduction of "Cold ironing" in the East Mediterranean to relieve the port from ship pollutions and going toward "greener" energy (e.g. renewables) to support the effort [15].

*Corresponding Author: Mohab Gaber, mohab_gaber@ieee.org

Using fuel cells for ship electric propulsion becomes a new challenger in the ship power system because it has good dynamic performance and maintenance-free so it's recommended in autonomous ships. On the other hand, limiting the power of fuel cells is another issue so fuel cells are used as an emergency source in the more electric aircraft techniques and special missions in naval ships that need a low acoustic signature like submarine seeking [16].

Improving the dynamics and power density of fuel-cell systems required to be combined with energy storage systems such as supercapacitors and batteries.

Another technique to enhance the performance of the fuel cell hybrid system by adding a renewable photovoltaic array that can reduce fuel consumption to 50% [11].

The system optimization is accomplished by an energy management strategy (EMS), to achieve economic fuel consumption and ensure providing the load with sufficient energy. Another factor is to maintain the system lifetime for each of the hybrid power systems as long as possible [17].

The advance of power systems that use renewable energy resources besides the revolution of power electronics forced fastly the development of artificial intelligence techniques [18, 19].

Using Artificial intelligence in the power system in operation, transmission, transient, protection, and control increases the stability of the power system, improves its output efficiency, and ensures system protection than classical protections [20-22].

The system proposed in this work is state of the art and the most common system used in different applications in industrial, aerospace [23], terrestrial, marine applications, and recently in traction systems. the difference between these systems is the energy management techniques.

Using adaptive neuro-fuzzy inference system in ship's power system combined the advantage of fuzzy and neural technique these procedures used to recognize the scheme Fault Analysis [24], estimate the system worth [25], development the power system effectiveness and lately to achieve the energy generated from the hybrid system to accomplish the economical use of fuel with best system performance. ship's electric power system is the same as any power system and starts the competitor of the improvement with a terrestrial power system [26].

In this system, the load demand and the battery state of charge (SOC) are the (EMS) input for identifying the adequate fuel cell power as system output based on solving the optimization problem to reduce the fuel consumed and ensure the system balance.

2. Ship smart grid power system

The ship's electric power system can be considered as an island microgrid during sailing and grid connecting in the port. Complex problems due to the existence of more than non-homogeneous power sources in hybrid systems had the solutions is the smart grid which is an important application in artificial intelligence (AI) and computational intelligence (CI).

In naval and commercial ships, the higher amount of information for the propulsion system, service equipment, and combat system naval ships need to be processed to decide the decision, AI and CI offer perfect solutions by centralized or distributed intelligence. The huge amount of information processing in the smart grid systems with computation intelligence (CI) for supporting the decision.

Artificial intelligence is working as a human brain that concerning decision-making capabilities such as search methods, knowledge representation, inference techniques, and machine learning [27].

CI techniques contain expert systems, genetic algorithms (GAs), fuzzy logic, artificial neural networks (ANNs), and adaptive neuro-fuzzy interface system (ANFIS). CI includes adaptive mechanisms for intelligent behaviors in complex systems, such as the ability to adapt and generalize. These techniques provide a new challenger for the field of ship smart grids and the application of the computer in power engineering.

AI and CI offer the best tools for the shipboard operation, maintenance, monitoring, in addition to risk management.

Ship smart grid technologies manage the uncertainties, increasing complexity, and highly nonlinear nature of hybrid electric power systems such as in-vehicle applications, and also in Autonomous Vehicles [23, 28, 29]. The adaptive Neuro-Fuzzy Interface system (ANFIS) which we use in this work, is an Artificial Intelligence technique that mimics human brain behavior. Due to its learning and generalization capabilities, ANFIS can be expressed as a mathematical representation of the human neural architecture. The accuracy of the energy management system in naval electric ships is important to ensure the availability of power in all modes of operations [30].

The adaptive neuro-fuzzy inference system (ANFIS) is a fuzzy inference system that uses a hybrid learning algorithm for training. ANFIS is a powerful technique used for predictive control and energy management in critical applications such as More Electric Aircraft (MEA) and hybrid smart grid [31] and in the systems that consist of Fuel cell and battery in different applications [32], [33]. As the industrial revolution and technology base for communication increases, electric shipboards power can be easily interfaced with a comprehensive computer program to handle energy saving and monitoring smartly and can also be used as fault diagnosis. The Internet of things makes interface these systems simple for navigations, especially in naval and autonomous ship applications in case of hazardous or dangerous locations, with a safe communication system for control and remote control [34].

3. System description

In naval ships, one of the difficult missions during sailing is the "submarine seeking" this mode of operation requires silent sailing performing a low acoustic signature to avoid submarine torpedo and missile because of the torpedo and missile lock on the ship noise.

The proposed model is a common hybrid model[23] consists of the main DC power source from a fuel-cell and storage system of

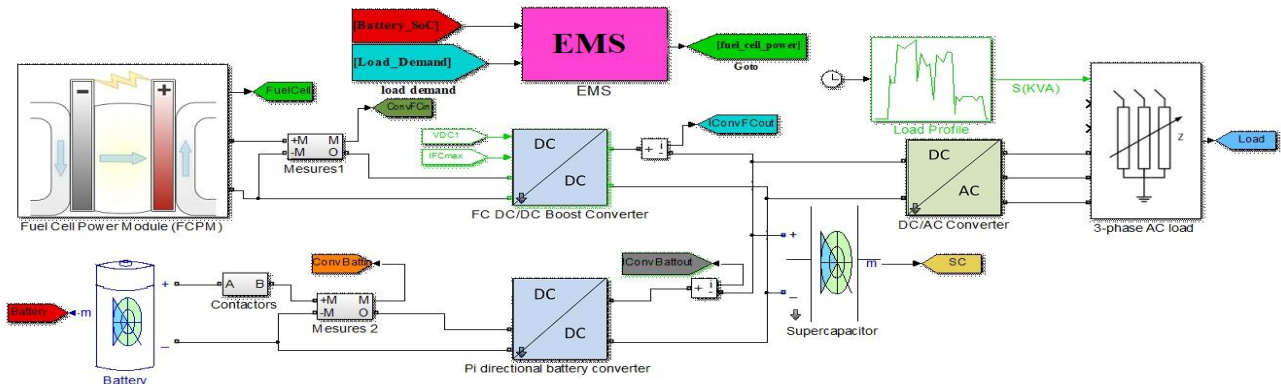

Figure 1: The model of hybrid power system for ship's silent mission

battery banks and super-capacitor. This model is enhanced by adding another energy source as a solar energy source (PV module) or diesel generator according to the ship application and the load demand.

The proposed hybrid model is designed based on the power requirement for the silent mission. The absence of mechanical equipment results in low acoustics signature the model as shown in Figure 1.

A 12.5 kW proton exchange membrane (PEM) fuel-cell power module, the system is designed to meet the average demand of 10 kW, to compensate for the slow dynamics of FCPM an energy storage system is incorporated with two series battery type Sonnenschein A 412/100 A (13.6 V, 100 Ah) working alone or with super-capacitor (48.6 V, 88F). The fuel-cell energy and battery energy are controlled across dc/dc converters which are determined by the output voltage reference and a max input/output current reference (fuel cell output power) from the energy management. The battery converter is bi-directional to charge/ discharge the battery the super-capacitor is neglected in this energy management system due to the short using time. The DC bus is the output of the two converters and connected to the input side of the inverter which converts the dc power to three-phase output power controlled the voltage and the frequency connected to programmable load profile power. This system is a generic system used in different applications with different power ratings with different energy management techniques. It is used in the more electric aircraft techniques and traction for trains and electric vehicles.

4. Energy management system architecture

The Architecture of the proposed Energy Management System (EMS) is as shown in Figure 2 where the ANFIS controller has two inputs and one output. The inputs to the EMS are the load power P_{load} and the battery State of Charge SoC, these inputs injected into the EMS to sense the performance of the system toward the loading and calculate depending on the training data the predictive energy from the fuel cell P_{fc} .

The load in the model can be modified according to the ship operation. depending on the experience, the load is pre-set to the model by programmed load profile and measure from the three-phase sides. A three-phase inverter with a sufficient rating

converts the DC power to AC power with controlled volt and frequency. The predictive fuel cell power is used to measure the max fuel cell current which is injected into the fuel cell DC/DC converter as a reference to the fuel cell converter. the max fuel cell current is injected into the fuel cell controller to calculate the sufficient amount of hydrogen fuel and air needed for the fuel cell as shown in Figure 2.

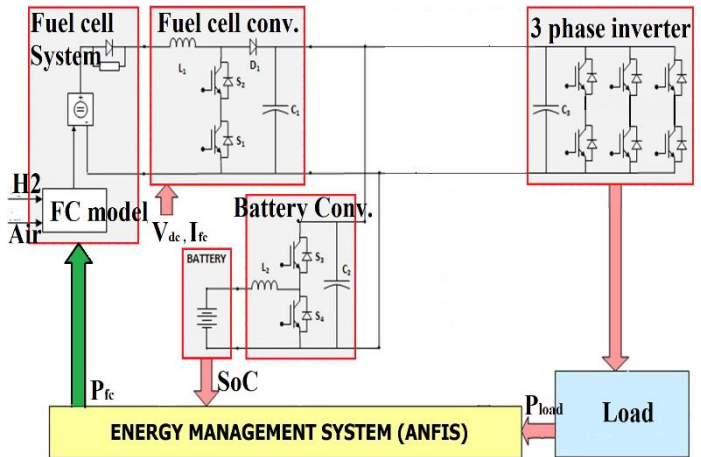

Figure 2: The architecture of the energy management system

The DC/DC battery converter is a bidirectional converter with two modes charging and discharging the controller to calculate the necessary battery current according to the battery SoC and determine which mode is active. Table 1 show the energy management-designed parameter requirement.

Table 1: Energy Management Design Parameter.

Parameters	Minimum	Maximum
Fuel cell power	1	10
Battery Power	-2.4 KW (charging)	4 KW (discharging).
Battery SoC (high)	85%	100%
Battery SoC (normal)	65%	85%
Battery SoC (low)	40%	65%
DC bus Voltage	250V	280V

5. System optimization problem

Hybrid systems that use at least two energy sources for providing the load with its needed power. that system is usually

combined with one or more renewable energy sources, energy-storing systems, or fuel systems that may be the engine with fossil fuel or hydrogen. Hybrid systems are expected to have an optimization technique working with the (EMS) which identifies which source provides the load with its necessary power or how much power should provide for each source to reduce the fuel consumption and ensure the system stability[35]-[37].

For achieving this goal, the optimal minimization and control strategy is applied to the hybrid system component fuel cell, supercapacitor, and battery to produce the reference power determined by the EMS based on the load demand[23]. The electric power produced from the fuel cell and the energy storing system battery and supercapacitor should be converted to equivalent hydrogen consumption.

The calculation of the equivalent of the hydrogen consumption for load C that is the sum of fuel cell hydrogen consumption C_{fc} and battery hydrogen consumption C_{bat} and supercapacitor hydrogen consumption C_{sc} .

The equivalent mathematical problem for minimizing fuel consumption is the following:

$$P_{fc} = \min (C_{fc} + k_1 C_{bat} + k_2 C_{sc}) \quad (1)$$

where P_{fc} fuel cell output power
 k_1 and k_2 penalty coefficients converter to hydrogen consumption.

The supercapacitor power is neglected in the optimization problem because the battery converter controls the dc-bus voltage. And the discharging or charging of the supercapacitors within the same energy from the battery system so the load power is divided between the fuel cell and the battery in each cycle. The optimization problem can be written as:

$$x = [p_{fc} + k_1 P_{batt}] \quad (2)$$

To minimize the equation

$$F = [p_{fc} + k_1 P_{batt}] \cdot \Delta T \quad (3)$$

The battery equivalent hydrogen consumption C_{bat} can be calculated from the battery power P_{bat} and the battery SoC Under the equality constrains

$$P_{load} = P_{fc} + P_{batt} \quad (4)$$

$$k_1 = 1 - 2\mu \frac{(SoC - 0.5(SoC_{max} - SoC_{min}))}{SoC_{max} - SoC_{min}} \quad (5)$$

With the boundary constrains

$$P_{fcmin} \leq P_{fc} \leq P_{fcmax} \quad (6)$$

$$P_{battmin} \leq P_{batt} \leq P_{battmax} \quad (7)$$

$$0 \leq k_1 \leq 100 \quad (8)$$

The above is the system cost function which is a generic problem for any hybrid system consists of fuel cell energy storing devices and this multi-objective optimization problem is solved for this system in several papers which is not interest in this issue [36], [38], [39].

6. Proposed (ANFIS) energy management system

With the spread of fuzzy techniques in the control applications, the developers look for an automatic learning process to supporting the industrial applications. The Adaptive Neuro-Fuzzy Inference System (ANFIS) was a solution to combine the advantage of both the learning ability of artificial neural networks (ANN) and the inference capability of rule-based fuzzy logic control to obtain a complete set of all kinds of feed-forward neural network with supervised learning capability. ANFIS technique achieves the hybrid learning procedure between the input-output relationship depend on the expert knowledge and input-output data. ANFIS become effective in modeling the nonlinear systems, identifying the nonlinear parameters in real-time control in the complex control in the complex electrical system, called Integrated Power System (IPS), which can be considered equivalent to an islanded power grid, and predicting the parameters like course keeping autopilot in ship sailing and weather forecasting [31], [32].

Figure 3 The proposed (ANFIS) structure

MATLAB provides a powerful simulation and test platform which will be used in this work. Figure 4. shows the structure of the MATLAB layered ANFIS implemented in this model. ANFIS design contained just one hidden layer as shown in Figure. 3, the system is composed of five nodes, layer_1 the input nodes, Layer_2 the fuzzification nodes, Layer_3 the product nodes(hidden), layer_4 the defuzzification nodes, and Layer_5 the output node. Besides, some nodes will be classified as adaptive or fixed nodes based on whether they can be updated.

Later_2 and Layer_4 denote as the adaptive nodes and Layer_1, 3 are the fixed nodes. To predict the power output of the fuel-cell, the inputs to the ANFIS are the battery SoC in three MF, and the consumed ship power load P_{load} . The output of the ANFIS is the predicted output power from the fuel cell value PFC. By applying the relative parameters, the ANFIS generates the rules and tunes efficiently.

7. ANFIS Control Procedure

ANFIS procedure will be carried out according to the learning result that pre-obtained from the old trial or human experience and this is the benefit of using ANFIS, especially the non-linear systems and the systems that need a quick decision in real-time.

In this system, the generic energy management system will introduce independent on the application the system with fuel cell and storage system (battery, super-capacitor) can be used in aircraft, ship or cars the only difference is the objective of the EMS for Aircraft safety is the highest objective for naval ships the reliability is the highest objective for cars minimizing the fuel consumption.

Two inputs are the EMS's inputs see Figure 4. The first input is the battery SoC that indicates the battery state and the amount of power that it has, the optimal state is the normal state between 65% to 85% [34]. Another objective is to maintain the battery state of charge SoC within normal SoC to increase the battery lifetime. The second EMS input is the ship's load power. The permissible fuel cell power between 1-10 kW to ensure the system balance.

Figure 4: MATLAB Simulation ANFIS Model

Figure 5: The MATLAB Simulation Output Surface of The ANFIS.

ANFIS model contained a closed-loop control system depends on the previous expert data. The accuracy of the system output is affected by ANFIS training data. In this system, ANFIS is trained to get the membership function (MFs), by (2352) training data among SoC, load power, and the fuel cell power to allow the

ANFIS to estimate a good correlation between inputs and output. The expert data entered into the system (3x784) input-output trial is used to develop the controller with minimum error.

To minimize the error (6000) epochs is performed to minimize the training errors till (1×10^{-4}) the training error less than 0.0001 this means the ANFIS system output is almost the desired concerning the training values. The output surface obtained from the ANFIS is shown in figure 5.

8. Simulation test results

The simulation result will be carried out using the MATLAB ANFIS editor for three-mode SoC High, Normal and low the system parameters are shown in the Table 1.

For testing the EMS the load power will be changing as the load profile to obtain the estimated fuel cell power the EMS calculates the max fuel cell current ($I_{f_{cmax}}$) which is used as a reference to the fuel cell air and hydrogen controller to determine the amount of fuel needed for the fuel cell, ($I_{f_{cmax}}$) and (V_{dc}) are calculated references determine by EMS for the DC/DC fuel cell converter to control the DC bus voltage within the limits mentioned in Table. I and enabling the state of the bi-directional DC/DC battery converter charging or discharging according to the system parameters load, battery SOC, and the calculating fuel cell power.

Figure 6 shows the ANFIS MATLAB simulation editor in case of battery normal SOC.

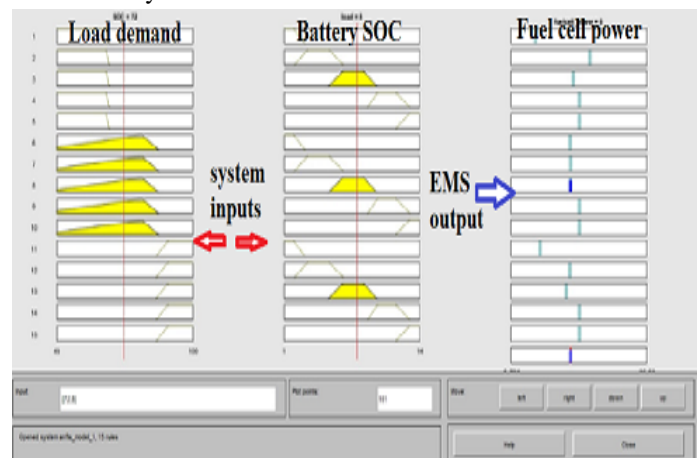

Figure 6: The MATLAB Editor Test

The simulation is carried out under three battery modes of operation. Table 2 shows the results obtained from the ANFIS editor in MATLAB the left column is the load demand changing from (1-12) kW. The second column is the EMS predictive power drawn from the fuel cell at high SoC mode 90%. The third column is the fuel cell's at normal SoC mode 75%, and The last column is the predictive fuel cell's power at low SoC mode 50%.

The battery State of Charge indicates the percentage of battery capacity. The battery power depends on the battery SoC, because that it should be balanced between charging/discharging in normal SoC mode to get better performance and for reservation its lifetime[40, 41].

Table 2: Simulation Result Obtained from ANFIS EMS

P_{load}	$P_{F.C}$ high SoC	$P_{F.C}$ Normal SoC	$P_{F.C}$ low SoC
1	1	1	2
2	1	2	2
3	2	3	4
4	2	4	4
5	4	5	6
6	4	6	6
7	6	7	8
8	8	8	8
9	8	9	10
10	10	10	10
11	10	10	10
12	10	10	10

Results in Table 2 show that the fuel cell power varies according to the battery SoC. ANFIS system is trained to provide the load with sufficient power and maintain the battery SoC in normal mode. the test had performed under their mode of operations high SoC at 90%, normal SoC 75%, and low SoC at 50%.

Figure 7: Fuel cell – Load Demand for Different Mode of Operations

The results obtained from the ANFIS system are shown in figure7.

The green line indicates the normal SoC mode of 75%. In this mode, the EMS produced power from the fuel cell equal to the load demand to supply the load and maintain the battery at its normal SoC.

The red line indicates the high SoC mode of 90%. In this mode the battery storage power is high so the EMS produces power from the fuel cell less than the load demand to supply the load and obtained power from the battery to reduce the battery mode from high SoC to normal SoC. The red line is under the green line (that indicates the load demand) because the fuel cell produced power (area under the curve) is less than the load demand and the remaining power is obtained from the battery.

The blue line indicates the low SoC mode in this mode the battery power is low so the EMS produced power from the fuel

cell greater than the load demand power to supply the load and charge the battery to increase the battery SoC from low to high SoC. The blue line is over the green line that means the power produced from the fuel cell is greater than the load demand.

In the third column the battery at normal SoC so the EMS produces power from the fuel cell equal to the load demand to maintain the battery SoC at normal mode. In the fourth column at low SoC, there is a shortage in the battery power so EMS produce power from fuel cell greater than the load demand to supply the load and charging the battery to increase the battery SoC from low to normal SoC.

The intelligent EMS trained to maintains the change in the fuel cell power in constant steps to avoid fluctuation in the ship electric grid. The intelligent EMS using the storage energy system to overcome the sudden and continuous change in load instate of step up or step down the fuel cell power because of the slow response of the fuel cell as a result of the chemical reaction.

EMS limiting the fuel cell output power at the maximum allowed the power of 10 kW although the load demand reaches 12 kW the remaining power is drawn from the batteries.

If the load demand exceeds this value, the protection device will disconnect the load.

9. Laboratory experimental simulation

To verify the proposed ANFIS Energy Management System control method in a real-time system, a test rig is built as shown in figure 8. with two dry gel lead, acid battery model Sonnenschein A412/100A 100Ah this battery offers excellent performance and suitable to work in marine applications and used in the field of unmanned surface vehicles USV. The battery will have been charged through a battery charger connected to the SOC sensor signal conditioner model 480E09 to indicate the battery state of charge.

Figure 8: laboratory test rig for ANFIS EMS.

Thermal loads 6X1 KW and three variable loads with 2X3 kW is connected to the system as system load smart Fluke multimeter is connected to the system to verify the drawn load the PC is plug in PCIe-6361 DAQ card connected to multifunction SCB-68 with 68 pins connected to the input and output signals SCB-connected to the PC across the data-parallel cable. The programmable power

supply working as a fuel cell to provide the system with the necessary DC power.

The input signal the pc is connected through the SCB-68 module as follow

- SOC from battery sensor conditional as 4-20mA.
- System load from smart Fluke multi-meter as RS232.
- The output signal 4-20mA connected to the programmable
- power supply through the yellow control cable as shown in Figure 8.

The power supply has two screens one for the DC voltage and the other is the power supplied from the supply.

NI-DAQmx9.2 drive software is installed on the PC to interface the system with the ANFIS.

10. Experimental test procedure

The schematic diagram of the system is shown in Figure 12. which shows the control modules contains from the PC with the DAQ system plug in the PC and the interfacing to the system sensor hardware through the cable and NI-DAQmx 9.2 software in the center of the diagram.

- The system inputs are in purple lines
- (P_{load} & battery SoC)
- The system output is green lines that indicate if the battery charging/discharging and the signal to the fuel cell to produce sufficient power to the system.

The test is carried out in three modes

- Battery SoC high above 85%
- SoC normal between 85 and 65%
- SoC low between 65% to 45%.

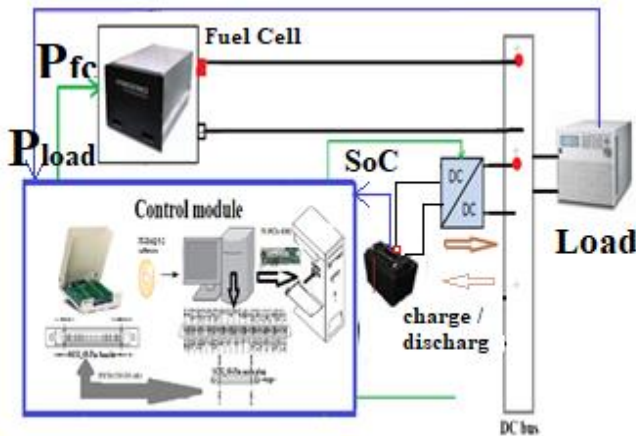

Figure 9: Structure for ANFIS Laboratory Test Rig.

For each mode of charge, the load will change manually from 0 to 12kW and the ANFIS sends the signal to the DC programmable power supply which is scaled before from 4-20mA control signal to produce power from 0-10KW.

The produced power is shown in the left monitor from the power supply as shown in Figure 8.

Table 3 shows the fuel cell power produced in the experimental test.

The experimental results show in Table 3 have the same concept in the simulation results in high SoC the EMS produces less power the demand load power to decrease the battery SoC to the normal SoC. The third column is the normal SoC which almost the load demand power to maintain the battery SoC at normal mode. The last column is the battery low SoC that EMS produces power from the fuel cell to charge the battery and supply the load.

Table 3: The Real-time Result Obtained from ANFIS EMS

P_{load}	$P_{F.C}$ high SOC	$P_{F.C}$ normal SOC	$P_{F.C}$ low SOC
1	0.9	0.95	1.9
2	0.9	2.01	1.95
3	2.05	3.01	3.95

10	10	10	10
11	10	10	10
12	10	10	10

10.1. Battery normal state of charge mode

In this mode, the battery SoC 90 % and starting to change the system load from 0 to 12KW the values obtained in this case in Table 3 will compare with the values from the simulation for the same SoC in Table .2. Figure 10. Shows the experimental results in red dashed line and the simulation result in blue dotted lines and the two curves are identical the same.

Figure 10: Real-time and Simulation Result at Normal SoC 75%

10.2. Battery high state of charge mode. 90%.

In this mode, battery high SoC 90 % mode and starting to change the system load from 0 to 12kW the values obtained in this case Table 3 will compare with the values from the simulation for the same SoC in Table 2. Figure 11. Shows the experimental results in the red dashed line and the simulation results in blue dotted line and the two curves are almost identical. The green solid line is the load demand.

Figure 11: real-time and simulation result at normal SoC 75%

10.3. Battery low state of charge mode 50%

In this mode, the battery low SoC 90 % mode and starting to change the system load from 0 to 12kW the values obtained in this case Table 3 will compare with the values from the simulation for the same SoC in Table 2. Figure 12. Shows the experimental results in the red dashed line and the simulation results in blue dotted line and the two curves are almost identical. The green solid line represents the load demand.

Figure 12: Real-time and Simulation Results at low SoC 50%

The results obtained from the simulation and experimental test are very closed to each other as shown in figures 10,11,12.

Figure 13: Percentage Error Between Simulation and Experimental Results

Comparing the values in table 2 and 3 the difference between the simulation results and the experimental results is the error which is very small and the maximum error about 10% at 1kW load demand that is because the chemical reaction in fuel cell takes times to produced power in the fuel cell starting. the difference between the simulation and experimental errors in the range between $[-0.02, 0.05]$ as shown in Figure 13.

11. Conclusions

This paper has developed the ship's electric power system by using both the environmental friend power source to reduce greenhouse gas emissions and to introduce environment-friendly energy sources based on ANFIS technique that combined the benefit of neural network for training and fuzzy inference for creating a correlation between input and output to analysis, training, and deciding for solving optimization problems depending on previous knowledge to reduce the fuel consumption

The non-conventional problems for protection, transmission, and diagnostic in a ship's electric power system take apriority to solve under Intelligent EMS and easy to interface with the ship's integrated power system.

ANFIS EMS technique is a powerful and easy to adapt than conventional EMS when adding or remove any system or device in the ship power system. Intelligent EMS easy to apply to any system have the same profile with little adaptation.

Verifying the result obtained from the simulation with the results obtained from the real test found it's the same gives more power to the system and this is the benefit of using intelligent system techniques.

This work is a part of past and future work that began with the designed hybrid energy management system, enhancement the system performance, and the user switched reluctance motor as propulsion motor. The future work is to use the simple and commercial embedded system "Raspberry Pi" as intelligent control and management for a hybrid ship power system.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The wide acceptance of the semantic web language RDF for ontologies creation in various application fields has led to the emergence of numerous RDF data processing solutions, the so-called triplestores, for the storage of RDF data and its querying using the RDF query language SPARQL. Such solutions are however developed under various perspectives and on the basis of various architectures. It is therefore a necessity for users to be able to distinguish between these systems to decide about the appropriate triplestore for an efficient processing of their RDF data depending on their objectives, the characteristics of their data and the technologies at hand. To this end, we give an extended categorization of RDF data stores according to their main characteristics. Furthermore, we review relevant existing triplestores within their respective established categories. The categorization is established according to the motivations behind the adoption of one or the other triplestore for handling the main tasks of data storage and SPARQL querying. Furthermore, the categorization considers various aspects that specifically deal with RDF data modeling, organization of RDF data, the processing of SPARQL queries, scalability, as well as aspects related to the diverse related data processing technologies.

1. Introduction

The “Resource Description Framework” (RDF) has been worldwide used during the last two decades for creating semantic ontologies in various application areas, and it is standardized by the “World Wide Web Consortium” (W3C) as the language of the semantic web ([https:// www.w3.org/ TR /rdf11-primer/](https://www.w3.org/TR/rdf11-primer/)). RDF represents data in the form of (S, P, O) triples to express the semantic information that an entity or a resource S is in a relationship through the relation or predicate P with an object O that is either a resource or a literal value. This modeling art lets then represent data as RDF directed labeled graphs where in each graph, resources and literal values are representing nodes of the graph and a node n1 is connected to a node n2 with an arc labeled by a predicate P if (n1, P, n2) is an RDF triple. To query the RDF triples, W3C also launched the standard language SPARQL (“Simple Protocol and RDF Query Language” - [https:// www.w3.org/ TR /sparql11-overview/](https://www.w3.org/TR/sparql11-overview/)). For interlinking purposes and for ontologies identification, entities are also endowed with URIs (Unique Resource Identifier). This mechanism has the advantage of assigning resources to groups, also called ontologies, and allowing interlinking resources of one group to resources of other groups yielding heterogeneous RDF data graphs.

It is exactly this simple semantic format offered by RDF to model data within ontologies that led to the transformation of the classical web to change it from a web of static pages to an intelligent web of interlinked data. The RDF format makes it indeed possible for machines to intelligently navigate inside the interlinked data since it enables formulating semantics about such data. Furthermore, the schema languages RDFS (“RDF Schema” - [https:// www.w3.org/ TR /rdf-schema/](https://www.w3.org/TR/rdf-schema/)) and OWL (“Web Ontology Language” - [https:// www.w3.org/ TR /owl2-syntax/](https://www.w3.org/TR/owl2-syntax/)), which are also W3C standards, do offer various semantic constructs to model the schemas of RDF data and allow intelligent navigation through such data using inference and reasoning techniques. RDF also offers various advantages for semantic modeling of enterprise data through its flexible schema definition and also offers a better alternative to the classical entity-relationship modeling approach [1], [2]. All these factors have led to the appearance of an important number of management systems for handling the storage and the querying of RDF data.

The abundance and variety of RDF data processing systems, also called triplestores, was also encouraged in a natural way by the emergence of various technologies such as NoSQL (Not only SQL - (Structured Query Language)), P2P (Peer to peer) and Big Data ones and was also imposed by the multiple varieties of RDF applications. A multitude of RDF triplestores have indeed been

*Corresponding Author: Khadija Alaoui, alaoui_khadija@outlook.com

developed, each with its own features that distinguish it from other triplestores. So, for a specific use case or application involving the use of RDF for data modeling, an appropriate RDF storage and processing system must however be well chosen from the multitude of existing RDF triplestores dependently of multiple factors.

In this sense, this work presents an extensive extension of the preliminary categorization of triplestores we gave in our conference paper [3]. The extension consists of a detailed categorization of RDF management systems with a review of relevant triplestores within their associated categories. Beyond the respect of RDF modeling constructs and implementation of elements of its query language SPARQL, RDF data management systems are filtered in accordance to the strategies used either for query processing or data storage. The strategies are enforced on one hand by the system architecture used if it is centralized or distributed, if it is a P2P, a cloud or a big data one. On the other hand, such strategies also depend on the adopted storage and querying methods, if they are relying on other existing data processing frameworks or if they are designed from scratch independently of any such frameworks. Furthermore, each category is presented according to the strategy used to handle RDF data storage and processing taking into consideration the structures used for its storage, indexing schemes and SPARQL implementation. For the organization of data storage, partitioning and indexing schemes are of particular interest since they affect the speed of query execution. This detailed categorization dependently of the data processing architectures and of the used systems characteristics and the targeted deployment machines represents therefore our main contribution in this work. The categorization with respect to such elements is of great importance for data management since they affect in a direct way the performance as well as the scalability of the triplestores at hand. To illustrate the given categorization we also review major relevant existing triplestores within their respective established categories.

The following sections of the paper are structured as follows. Section 2 presents the semantic web standards RDF, SPARQL, RDFS and OWL. Section 3 gives a summary of our categorization approach. Sections 4 to 9 present the main categories with their respective sub-categories. Section 10 summarizes the categories with a discussion on related works. Section 11 concludes this work.

Figure 1: Web semantic Architecture

2. Standards of the Semantic Web

In the following subsections we give a brief presentation of the web semantic standards. The focus is mainly on the main issues

related to these standards that are in a direct connection with the tasks of triplestores with respect to RDF data storage and query processing. Figure 1 shows the elements of the semantic web architecture.

2.1. RDF Data Model

The representation of data with RDF is based on modeling all information as a set of sentences of the form 'Subject Predicate Object' yielding triples (S:=Subject,P:=Predicate,O:=Object). Each triple (S,P,O) gives the meaning that the resource S is in a relationship through P with the object O. Objects can be either resources or literal values. In the example of figure 2, we have for example the triple (ex:Jabir,ex:teach,ex:java).

```
@prefix rdfs : <http://www.w3.org/2000/01/rdf-schema#>.
@prefix rdf : <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
@prefix xsd : <http://www.w3.org/2001/XMLSchema#>.
@prefix ex : <https://www.mySite.ma/example#>.

ex:teachingactivity rdfs:type rdfs:Class .
ex:unistaff rdf:type rdfs:Class .
ex:course rdfs:subClassOf ex:teachingactivity .
ex:teach rdf:type rdf:Property;
    rdfs:domain ex:lecturer;
    rdfs : range ex:course .
ex:weekhours rdf:type rdf:Property;
    rdfs:domain ex:course;
    rdfs : range xsd:integer .
ex:java rdf:type ex:course ;
    ex: weekhours 5.
ex:Jabir rdf:type ex:unistaff ;
    ex:teach ex :java .
```

Figure 2: RDF Example in N3-Notation

2.2. RDFS and OWL

RDFS offers constructs to describe elements of an RDF graph in a meta-model. The statements in the RDFS meta-model are also expressed as RDF triples. The meta-model declares the classes of resources and predicates used in the RDF graph. Ranges and domains of predicates can also be given in the meta-model. RDFS also offers the possibility of creating hierarchies between classes using constructs such as "subClassOf". For example, in the example of Figure 3, the class "ex:course" is declared as a subclass of "ex:teachingactivity".

OWL extends RDFS with many semantic constructs allowing the definition of more expressive RDF graphs and offering more reasoning possibilities on them. OWL meta-models are also expressed in RDF which makes the reasoning based on description logic easier. As examples of constructs in OWL we mention 'ObjectProperty' and 'DatatypeProperty' for the definition of types of predicates, and 'AllValuesFrom', 'SomeValuesFrom', 'ComplementOf' and 'DisjointWith' for constraints on domains and ranges of predicates. OWL also provides constructs for the creation of new types from other types as well as constructs for properties on predicates, for example, if they are invertible, symmetric or transitive.

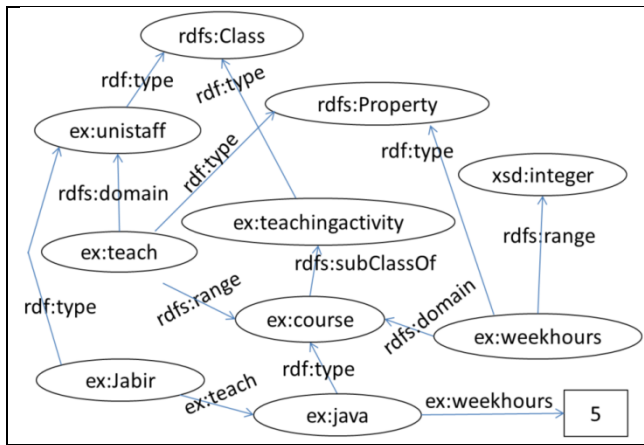

Figure 3: RDF Graph Example

2.3. SPARQL

To query RDF data, the query language SPARQL has been proposed and standardized by the W3C. SPARQL is very similar to SQL and can perform complex joins of various RDF data graphs in the same query. Figure 4 gives a simple example for looking after who teaches “java”.

```
Prefix ex: <https://www.mySite.ma/example#>
SELECT ?x
WHERE
  ?x ex:teach ex:java .
```

Figure 4: SPARQL example

Beyond SELECT queries to extract information from RDF data, SPARQL also offers ASK queries that return either true if the query condition is satisfied and false if it is not satisfied, and CONSTRUCT to add new triplets to RDF graphs as results of such queries, as well as DESCRIBE queries that extract information about a resource. SPARQL queries can also handle aggregations and may contain optional clauses with optional conditions as well as a FILTER clause to further filter their results.

3. Categorization approach

The categorization approach we are using is mainly based on the context in which RDF data is used. Within this context the following elements are considered:

- The storage technique used: We mainly focus on its adaptation to RDF model and for which environment it is used. With environment we consider the use of the solution on only one machine or on a cluster of machines and if the solution is for use in Cloud, P2P or desktop context.
- Nature of destination devices: we handle the case of using RDF data either in constrained devices, desktops or clusters.
- System scalability: we especially take into account the separation of solutions dependently on data volumes to be processed.
- Data organization: This point is very important since SPARQL queries may pose many challenges related among others to join and sub-graph processing especially when RDF

data are scattered among various graphs or stored in multiple files or in multiple nodes.

4. Native versus Non-Native Triplestores

Native RDF data systems are those systems that are built from scratch only for the purpose of handling RDF data without relying on any existent data management solution. This means that the solutions associated with such native stores are implemented independently of any existing specific database engine for the storage or querying of any kind of data. To achieve their tasks, native stores may however be built using functionalities of the file system under hand and of course existing programming languages such as C, C++ and Java.

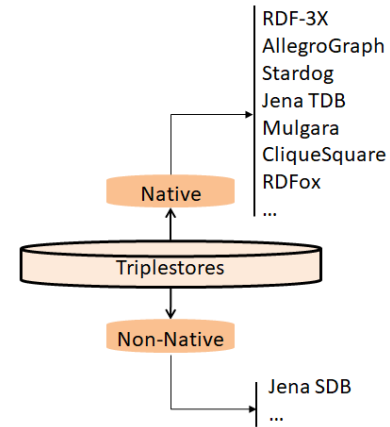

Figure 5: Catégorisation "Natifs / Non-Natifs"

In contrary, non-native triplestores are those stores that rely on already existing data management solutions such as, for example, relational, XML, NoSQL database management systems or also Big Data technologies for data processing such as HBase or Pig. Figure 5 illustrates the considered “native/non-native” categorization.

4.1. Non-Native triplestores

As examples of non-native triplestores we have Jena SDB (<https://jena.apache.org>), triplestores that are based on existing classical relational database systems and triplestores that are based on NoSQL database systems. The category of relational triplestores is treated in section 6.1 and the category of non-relational triplestore is considered in section 6.2.

The Jena framework is implemented in Java. It has been continuously updated since its launching in the year 2000. Jena uses a data structure called model to represent an RDF graph with associated methods to manipulate its nodes which can be resources, blank nodes or literals. Also Jena creates triples as instances of the Statement class.

Jena also comes with a reasoning module for inferencing based on some RDFS as well as OWL constructs and also based on rules that are defined by users. Furthermore, a Jena server called Fuseki is also provided for SPARQL querying over HTTP.

Jena SDB uses Jena APIs and JDBC for handling RDF data in a relational database system. It will be further detailed in the category of single-table relational triplestores category.

4.2. Native triplestores

As already mentioned, in contrast to non-native stores which are setup to run on top of other existing database processing solutions, native stores are built specially for the RDF model to provide persistent storage with own database implementation solutions. Examples of such native store are RDF-3X [4], AllegroGraph (<https://allegrograph.com>), Stardog (<http://stardog.com>), Jena TDB [5], Mulgara (<http://www.mulgara.org>), RDFox (<http://www.cs.ox.ac.uk/isg/tools/RDFox>) and CliqueSquare [6], [7].

AllegroGraph store uses RDF-XML and N-Triples to load the triples. The implemented query language is SPARQL, however external programming APIs can be used to find datasets matching specific triples.

CliqueSquare uses the distributed file system of Hadoop for storing data and its MapReduce implementation for the processing of RDF data.

5. Memory-Based versus Disk-Based Triplestores

Memory based triplestores, also called in-memory databases, rely on main memory for data storage. As the memory access is faster than disk access, these triplestores allow quick access to data and faster query execution. Memory based triplestores show therefore best performance since entire datasets are in memory.

Figure 6 shows the two considered categories which are presented next.

Figure 6: "Memory / Disc" Categorization

5.1. Memory-based triplestores

As the name indicates, main-memory-based triplestores fully load RDF data in main memory to do processing on it. Jena TDB, TrinityRDF [8], AdHash [9], ClioPatria [10] and ScalaRDF [11] are examples of memory based triplestores.

TrinityRDF allows the store of trillions of triples. It represents entities as graph nodes while the relations are represented as graph edges. Trinity supports parallel computing and handles massive number of in-memory objects as well as complex data with large schemas; however, it does not guarantee serialization for concurrent threads.

AdHash uses the principle of applying lightweight hash partitioning to distribute the triples by using a hashing according to subjects in order to limit the data communication costs for join queries. AdHash elaborates this by monitoring the data access

www.astesj.com

patterns and gradually redistributing and replicating the accessed data. By increasing the in parallel executed join operations, AdHash improves the queries execution time.

5.2. Disk-based triplestores

The triplestores in this category interact with RDF data through programs loading from disk the portions of data each time when they are needed. In this category we have of course those triplestores that use engines of relational database systems for processing RDF data such as Virtuoso [12] and 4store (<https://github.com/4store/4store>).

We also have Big Data RDF processing solutions that rely on Hadoop or Spark frameworks for managing RDF data and which will be presented in section 8.

6. Relational versus Non-Relational Categorization

During the first years of the semantic web, the focus was mainly on the use of relational database (RDB) systems for the storage and processing of RDF data on one hand for their dominance and on the other hand for the aim to benefit from associated during years developed technologies with respect to efficient data processing as well as to users APIs.

However, such use of these relational systems still face many challenges such as the need for efficient solutions to reduce the added time complexities due to the need of translating SPARQL queries into SQL ones. Also, there are still some difficulties faced by the semantic web world for the use of object oriented based application frameworks and programming languages. Furthermore, the dynamicity of RDF data generally poses a challenging problem to relational database designers since relational schemas generally rely on static schemas to model the tables of their databases.

6.1. Relational Triplestores

Relational RDF stores use relational database (RDB) systems to store and query RDF data. Figure 7 presents the categories of such stores which will be detailed next.

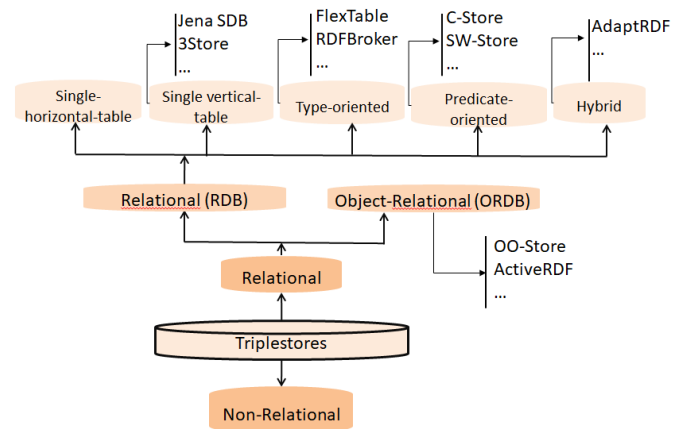

Figure 7: "Relational Triplestores" Category

Relational triplestores provide various advantages due to the technologies developed over decades for relational database management systems (RDBMs). Worth mentioning with respect to RDF data storage and processing is the indexing strategies (e.g.,

hashing, B/B+ trees) offered by RDBMs and query optimization techniques based on relational algebra operators as well as value typing. Also relational triplestores allow easy data integration of relational databases into RDF models or of other data sources with the use of existing data mapping and conversion techniques for transforming and storing such data sources into relational databases. A further positive point of relational triplestores is the possibility to use existing data analytics tools (e.g., machine learning, business intelligence) developed for RDBMs. However extensions in this sense are still to be considered in the context of the nature of RDF data.

Relational triplestores also suffer from the limitation related to the high processing costs due to RDF data loading in RDBMs and also to the need of translating SPARQL queries into SQL ones for data processing. Another drawback of RDF stores is that they are in majority centralized solutions which let them not to be adequate for massive RDF data management. A further negative point of relational triplestores is the lack of user involvement to use equivalent functionalities that are already offered to SQL users such as creation of indexes or programming interfaces.

6.1.1. Non-Object Relational stores

Since the beginning of the semantic web, various solutions to store RDF in classical non-object relational database (RDB) systems have been proposed. They mainly depend on how the RDF triples are distributed with the appropriate relational schemas. In the following we present the main sub-categories of RDB triplestores and their RDB used schemas to manage RDF data.

6.1.1.1. Single vertical-table RDB triplestores

This category contains those relational stores that store triples in a single table with a column for subjects, a column for predicates, a column for objects and possibly a column for graphs to which triples belong. In this category we have the triplestores Jena SDB, 3Store [13], 4Store [14], Sesame [15] and Hexastore [16].

Jena-SDB which is an RDB triplestore can be used with a large number of RDBs which let it benefit from the indexing capabilities provided by RDB. Applications may use JDBC connector to store RDF triples in Jena SDB. The use of Jena-SDB is only recommended when it is necessary to layer on an existing SQL deployment. However, if explicit transactions support is required, Jena SDB reuses the transaction model from the underlying relational database.

3Store has a query engine developed using the C language and it is implemented on top of MySQL. Hash tables are used respectively for resources, literals and graphs to encode such objects. Triples are stored in a single table that stores for each component of a triple its associated hash code that is used as a reference key to its entry in the associated table. RDF data can be accessed via RDQL based on an apache server interface and a query engine that translates RDQL query into SQL query.

4Store runs on a cluster. Its design is based on 3Store. Data in 4Store is stored as quads (G:graph, S,P,O) where G is the graph to which the triple (S,P,O) belongs. Triples in 4Store are partitioned using hashing on the identifiers of subjects. This partitioning strategy can however lead to nodes that are heavily loaded with

data than the others and may therefore lead to high query processing time costs.

6.1.1.2. Single-horizontal-table RDB stores

The systems of this category use a single table, also called predicate table, with a column for subjects and a column for each possible predicate. Each resource is then stored with all values of its associated predicates in one line of the table and NULL values for the other predicates. Therefore, this approach could lead to lines in the table with many NULL values resulting in large processing times.

6.1.1.3. Predicate-oriented RDB triplestores

These systems associate a relation with two columns with each predicate for its (subject, object) pairs [17]. C-Store [18] and SW-Store [19] are examples of such stores.

An advantage of this storing approach is that it is easy to implement and resolve the NULL values problem of single-horizontal-table. However this approach has the disadvantage that it comes with a huge number of tables which involves large number of joins in query execution.

6.1.1.4. Type-oriented RDB triplestores

These systems associate a relation with each RDF resource type (i.e., for each class of objects) with one column for subjects of this common class and a column for each predicate associated with such subjects. Triples with subjects not belonging to any class are stored together separately in a table of three columns respectively associated with subjects, predicates and objects. FlexTable [20] and RDFBroker [21] are examples of such stores.

RDFBroker is based on occurring predicates signatures in RDF data. The set of predicates that occur with a resource in the triples is called its signature. These signatures together build the signature of the graph. A signature graph is then constructed with nodes being the signatures, and an edge from one signature to a second one means that the first signature is a subset of the second one. RDFBroker then creates for each signature in the graph a table with a first column for the subjects appearing with the signature predicates in the RDF data triples and one column for each of these predicates. Triples are then put in the suited table according to the signature of their subjects. Such a strategy does remedy to the problem of NULLs posed by the single-horizontal-table approach.

6.1.1.5. Hybrid triplestores

Hybrid triplestores consist of stores that use combination of previous approaches. Within this category, we principally have stores that cluster the predicates that appear together with respect to a clustering criterion. For each cluster of predicates, a table is created with columns represented by the cluster predicates and a column for the subjects, and triples with these predicates are put together in this so-called property table. To store the triples with the remaining predicates, which are not clustered, a single-vertical-table is used.

AdaptRDF [22] is an example of hybrid triplestores. It uses a single vertical table as well as property tables. First all triples are put in the vertical table and with respect to the queries load property tables are created to partition the vertical table and further dynamically adjusted with respect to predicates based on a

mathematical process which considers the query workloads over time.

6.1.2. Object Relational Stores

Object relational databases (ORDBs) offer the possibility to encapsulate data within objects. They also give methods to serialize objects, generally as key value associations, or compound values. ORDBs are specially needed in fields with complex data objects and objects interactions with data represented as a collection of objects.

Conversion and storage techniques from RDF into ORDBs have mainly been inspired from previous similar works on the processing of XML documents in ORDBs. One solution in this sense is the one proposed with its prototype in [23]. In this solution, for each document a model instance of a class Model is created to manage the elements of the document. A class Resource is defined to instantiate a resource or a predicate and a class Literal is used to instantiate literals. All these three classes are subclasses of a class Node which gathers common attributes. Also a class Statement is provided for instantiating triples with Node-components. Using these classes, the various elements of the RDF document are scanned and stored as objects using the methods of the class Model.

Also worth mentioning are OO-Store [24] which is proposed as a prototype implementation for the processing of RDF data based on ORDBs, and ActiveRDF [25] which also comes with programming elements for the management of RDF data.

All object oriented relational RDF solutions with their OO programming constructs have the advantage of being open for possible further extensions to interact with the widely developed object oriented solutions either for data engineering or data accessing (e.g., UML, Spring, hibernate, ..) as well as with other programming languages. Also ORDB triplestores do profit from the advantages offered by RDBMs. Ways are however still needed to extend such triplestores with object oriented graph APIs for an object oriented programming perspective within the context of RDF data.

6.2. Non-Relational triplestores

Some of the key factors that have motivated the looking for other types of RDF processing systems other than relational ones are of course the limitations of RDB systems with respect to the variability that needs dynamic and flexible schemas other than static RDB schemas.

Figure 8 illustrates the categorization of such systems whose sub-categories are presented in the following subsections.

6.2.1. Binary Triplestores

The class of binary stores consists of triplestores that use bits to encode RDF triples. BitMat [26] and TripleBit [27] are two examples of such stores.

In BitMat each line of the matrix is associated with one subject and each column is associated with one predicate. Each entry in the i -th line and j -th column of the matrix is a sequence of bits from the set $\{0,1\}$ with only one bit 1 whose position k representing the presence of the triple (i -th subject, j -th predicate, k -th object). BitMat benefits from the use of 0-1 sequences for representing RDF triples to use them to compress the RDF data. Querying of RDF data is done in two steps in BitMat. Candidate matches are derived from the bit matrix in first step and the exact matches are returned in a second step. Though the advantages offered by the bit representation and the possible compression on it, this technique still needs however to tackle the problems faced by insertion or deletion of RDF triples.

6.2.2. NoSQL-Document triplestores

Document stores, like MongoDB and CouchDB, do use documents to persist data. A document is organized as a collection of fields where each field is associated with a set of values. Each one of the fields could be used as an index for data retrieval.

The RDF triplestores D-SPARQ [28] and RDFMongo [29] are examples of document-oriented store that use MongoDB.

Another NoSQL document solution for processing RDF data which we call CouchbaseRDF was presented in [30] to store RDF data in Couchbase (<https://www.couchbase.com>) which is a JSON-based document store.

6.2.3. NoSQL-Key-Value triplestores

The category of NoSQL-key-value triplestores consists of those RDF stores that use a NoSQL key-value database system for storing and querying RDF triples. NoSQL key-value database systems store data as collections of key/value pairs and offer `get(key)` and `put(key, value)` access methods to read and write data. Redis (REmote DIctionary Server - <https://github.com/redis/redis>) and DynamoDB (<https://aws.amazon.com/fr/dynamodb>) are examples of key-value NoSQL database management systems. Redis is an in-memory data management system. DynamoDB offers various characteristics such as replication and buck up of data and the possibility of its integration in web applications.

An example of NoSQL-key-value RDF stores using Redis is ScalaRDF which is also a distributed and memory-based store. As an example of triplestores using DynamoDB we have AMADA [31].

6.2.4. NoSQL-Graph triplestores

Graph oriented triplestores simply use the graph representation of RDF data and store these data as directed graphs where the nodes are either resources or literals and an edge starting from a node $n1$ to a node $n2$ is labeled with a predicate p to mean that $(n1, p, n2)$ is a triple.

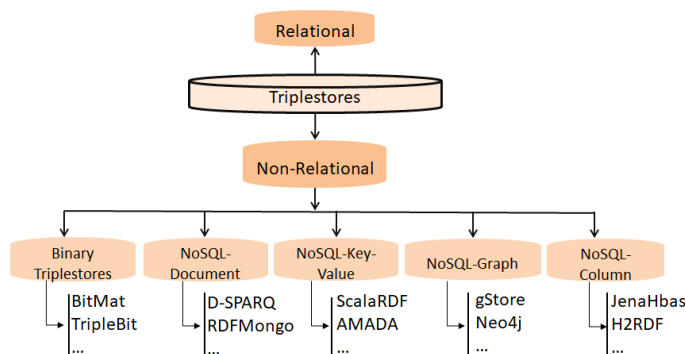

Figure 8: Category of Non-Relational Triplestores

In the family of NoSQL-graph triplestores we have gStore [32], Dydra (<http://dydra.com>), AllegroGraph, BlazeGraph (<http://blazegraph.com>) and S2X (SPARQL on Spark with GraphX) [33].

The triplestore gStore is a centralized graph-oriented solution that uses bit-encoding to encode RDF triples as well as to encode SPARQL queries in the same way. Codes of SPARQL queries are then simply matched to the encoding list of RDF data. gstore has also been extended to a distributed solution called gStoreD.

AllegroGraph is a high performance triplestore that is continuously updated and extended. For data retrieval, it organizes data in Repositories, associates an identifier with each triple, and stores each triple as a quad composed of the values for subject, predicate, object and the graph to which the triple belongs. Furthermore, it uses all combinations of these 4 components to which the identifier is added as default indexes. A query in Allegrograph is first analyzed to determine the indexes that may be involved by the query. The actual indexes used by the query are dynamically identified in a second processing step. Allegrograph also supports reasoning and transaction management.

6.2.5. NoSQL-Column triplestores

The list of column triplestores comprises among others “Jena-HBase” [34], H2RDF+ [35], CumulusRDF [36] and Rya [37].

The triplestore “Jena-HBase” is built on top of HBase column store and is discussed in the Hadoop-nonnative Big Data triplestores category. H2RDF+ and CumulusRDF use the Cassandra column database. The triplestore Rya uses Accumulo.

7. Centralized versus Distributed Categorization

Various RDF stores have been designed to ensure efficient and scalable RDF query processing in a centralized way. Centralized systems manage the storage and querying on a single node. Hence, their main advantage is that they handle all operations locally. However they face the inconvenient of limited resources due to the using of a single machine.

Distributed triplestores use multiple machines for the storage and querying of RDF data. They have therefore the capability of handling large amounts of data.

Both categories with their characteristics are presented in the following subsections, respectively.

7.1. Centralized triplestores

Centralized triplestores use a single machine to handle RDF data. The centralization is of course with respect to data storage as well as SPARQL processing. Figure 9 presents the sub-categories of the centralized triplestores category.

As their name suggest, the main drawback of centralized triplestores is the lack of scalability and fault tolerance.

7.1.1. Desktop triplestores

With desktop triplestores we mean those RDF management systems that run on single desktop machine such as RDF-3X and Hexastore.

Figure 9: Category of Centralized triplestores

Hexastore combines the relational vertical representation approach with indexing capability to ensure fast querying of RDF triples. Indeed it uses each possible combination of the components “subject”, “predicate” and “object” for indexing.

7.1.2. Mobile triplestores

This category of RDF stores consists of course of triplestores built especially for managing RDF data in mobile devices such as RDF-on-the-Go [38]. The flexibility and simplicity of the RDF data model make it as a good candidate for data interaction within and between such mobile devices.

RDF-on-the-Go is a full-edged RDF storage system that allows RDF storage and SPARQL query processing for mobile devices. RDF-on-the-Go relies on Jena and the Semantic Web Toolkit ARQ. It stores triples using the Berkeley DB. Its indexing strategy is based on the use of R-Trees.

7.2. Distributed RDF Triplestores

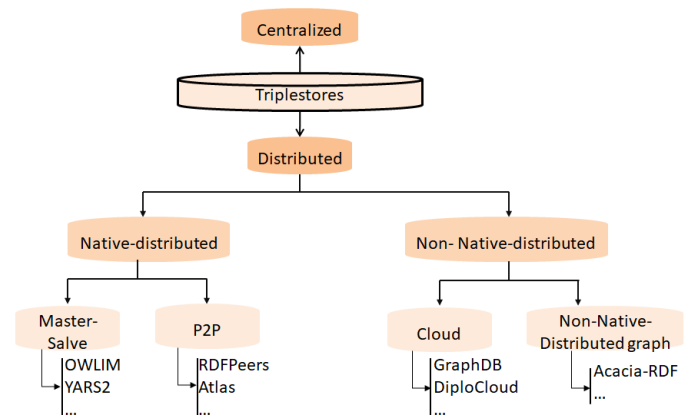

Figure 10: Categorization of Distributed Triplestores

Distributed triplestores are of course those systems that use more than one node to manage RDF data. The distribution concerns either the task of storage alone, the task of query processing alone or both tasks. Data distribution needs choosing efficient RDF data partition strategies that are also in accordance with the data retrieval modes chosen for querying the RDF data in order to achieve rapid RDF data manipulations. Issues involved are mainly related to data partition, data exchange between nodes, processing load partition and failure handling. The speed of RDF

data processing is mainly influenced by such issues. The strategies to address such issues have to be well chosen to better control the communications between nodes which can lead to high costs and to minimize data processing times within single nodes.

Figure 10 illustrates the distributed categories of triplestores.

7.2.1. Native-distributed triplestores

Native-distributed systems are considered here with respect to the distribution only and are those triplestores that come with their own distributing approaches for both storage distribution and query processing distribution.

7.2.1.1. Master-Slave native-distributed RDF stores

This category is composed of those triplestores that are built independently of any data management already existing solution and follow the master-slave distribution principle where RDF data management is in control of a master node that distribute management tasks to slave nodes. Examples of such triplestores are Virtuoso Cluster Edition, OWLIM [39], YARS2 [40], TriAD (Triple Asynchronous Distributed) [41].

OWLIM with its variants is developed with the java programming language and is a native RDF store. Its variant SwiftOWLIM is rather a memory based centralized triplestore. Its cluster version BigOwl is distributed and contrary to other distributed triplestores handles deletion and insertion of RDF data more efficiently with the help of its indexing and partitioning strategy. It is currently developed under the new name of GraphDB (<http://graphdb.ontotext.com>) which also belongs to the category of cloud triplestores.

YARS2 is a native distributed RDF store. It proposes distributed indexing methods and three forms of indexes: Keyword index, six quad indexes and Join indexes.

TriAD also uses a classical master-slave architecture with a direct communication through the asynchronous exchange of messages. TriAD uses METIS graph partitioning with respect to subject and objects and associated combinations of indexes. Queries in TriAD are optimized using a summary graph that takes in consideration the result of the partitioning in order to execute queries directly only on concerned parts of the RDF graph.

7.2.1.2. P2P triplestores

P2P (peer to peer) defines a distributed model for a network of computers in which computers, also called nodes, play an equal autonomous role with regards to responsibility in the network and share their resources with the other nodes. In a P2P system, there is no single master node for managing the distribution traffic between the nodes. Computing services, data management and networking are offered in a decentralized way and are therefore not controlled centrally like in master-slaves networks. Beyond this decentralization, both fault-tolerance and scalability are the main advantages of P2P systems.

Examples of P2P based RDF data management systems are RDFPeers [42], Atlas [43], Edutella [44], RDFCube [45], GridVine [46] and UniStore [47].

The main problem faced by P2P triplestores is how to get a balanced distribution of RDF data between nodes for an efficient

retrieval and querying of data and in order to avoid that some of nodes get heavily loaded with data more than other nodes.

Hashing is a common indexing solution that is used for distributing and tracking RDF data. Triplestores do however differ in their adopted hashing strategies. The hashing does of course guide the distribution but dependently of the used hashing method it however may lead to imbalances of load between nodes. In this case, the strategy is generally completed with a local split procedure at each node to achieve a uniform distribution of RDF data and therefore to a balanced querying of the RDF data. Once exceeding a threshold of stored data a node launches its split procedure to achieve a uniform data distribution.

Another crucial task for a P2P store is the maintenance of the hashing information during the processes of data suppression, update and insertion.

Apart from this burden caused by hashing tasks, generally speaking P2P triplestores beyond scalability show robustness with respect to fault tolerance and the advantage of not being centralized controlled.

7.2.2. Nonnative-distributed triplestores

The nonnative-distributed triplestores, as the name suggests, rely on existing distribution frameworks for the processing of RDF data. On one hand, we have those triplestores that use cloud solutions that are presented next, and on the other hand, we have triplestores that are relying on Big Data frameworks which are presented in section 8.

7.2.2.1. Cloud triplestores

During the last years, cloud computing has acquired more interest by users due to its flexibility, costs and availability of computing resources. Indeed numerous cloud computing providers have evolved and are offering numerous computing software and making available powerful machines to users. Furthermore, cloud computing has many advantages such as hiding from users all the complexity of distribution and handling of problems related to fault tolerance or others. Within the framework of RDF data management, numerous triplestores relying on cloud solutions have also been developed. Among these we have GraphDB (<http://graphdb.ontotext.com>), AMADA, H2RDF [48], Rya, Stratiore [49] and DiploCloud [50].

GraphDB is an RDF database system that runs on the AWS cloud. It provides easy on-demand access for semantic metadata.

DiploCloud represents an RDF graph is generated on three main structures, namely RDF molecule clusters, template list and key index.

7.2.2.2. Nonnative-Distributed graph triplestores

This category is constituted of those RDF systems that use graph oriented solutions for RDF data management in a distributed scenario.

Acacia-RDF [51] is an example of such triplestores. It also has implementation of various algorithms for handling graphs. Furthermore, it can also be run on a single node. Acacia-RDF relies on the graph database solution Acacia and is programmed in the language X10. It can also be used as a centralized triplestore.

8. Big Data Triplestores

In recent years, various solutions have emerged for the processing of huge amounts of data with the use of clusters made up simply by commodity computers. Such solutions are also offering programming tools for accessing and processing the large data scattered in their distributed file systems based on well-defined frameworks.

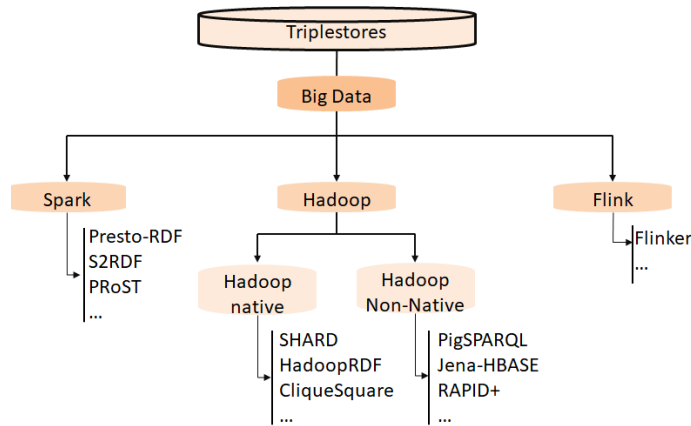

Figure 11: Category of Big Data Triplestores

The categorization of Big Data triplestores we are giving here is made with respect to the Big Data processing solution used by each one of these triplestores. More precisely, we distinguish between those triplestores that are based on Hadoop, Spark or Flink. The adoption of each of these systems by a triplestore will be clarified in the associated category subsection taking of course the characteristics of the system considered. The sub-categories within the Big Data category are presented in the following subsections and are illustrated in Figure 11.

8.1. Hadoop triplestores

The Hadoop triplestores are triplestores that are built on Hadoop HDFS (Hadoop Distributed File System) and Hadoop MapReduce programming framework for the storage and processing of RDF data.

In the following subsections we give the associated subcategories and highlight the main principles on which the storage structure and querying are based. Three subcategories are identified taken into account if they are relying on a direct use of HDFS and MapReduce completely or only partly with the use of other intermediary solutions.

8.1.1. Hadoop-native triplestores

Native HDFS-MapReduce triplestores are not relying on any already existing solution that uses Hadoop either for storing or querying data. They are built from scratch for the use of the HDFS file system to store RDF graphs and MapReduce for execution of SPARQL queries.

In the category of Hadoop-native triplestores we have SHARD [52], HadoopRDF [53] and CliqueSquare.

HadoopRDF stores RDF data triples into HDFS based on a predicate-oriented partitioning and performs decomposes queries respectively in MapReduce jobs. It keeps as many joins as possible

in each job to reduce the number of jobs. This strategy can lead to high time costs especially when the value of predicates are unknown and multiple files have to be uploaded in this case to process queries.

SHARD is also a Hadoop-triplestore that distinguish itself by the subject oriented RDF data storage and an iterative query processing which is also subject-oriented. For each subject it stores all its triples with their predicates and objects in one line. For processing a query, it creates a pattern matching job for each triple pattern in the query and executes a join with the result computed up to this job. This strategy leads of course to enormous running times.

8.1.2. Hadoop-nonnative triplestores

With the category of Hadoop-nonnative triplestores, we mean those triplestores that directly use other existing HDFS/MapReduce general data management solutions for the handling of RDF data. Examples of RDF stores in this category are PigSPARQL [54] and RAPID+ [55], [56], “Jena-HBase” and “Hive+HBase” [57].

The triplestore “Hive+HBase”, for example, uses functionalities of HBase that uses HDFS for managing data and Hive that also offers a data warehousing module.

The reliance of Hadoop-nonnative triplestores on other existing Hadoop data storage and processing existing solutions is an advantage of such triplestores since such solutions are for use in a general context and offer therefore to the triplestores possible ways for further development with components related for example to integration of other data sources and for incorporating other functionalities related to data analytics and also to transaction management.

However, the major drawback for both Hadoop-native and Hadoop non-native triplestores is the high communication costs because of unavoidable disk input and output operations during the execution of the task of MapReduce jobs phases when dealing with massive RDF data. In the case of Hadoop-nonnative triplestores, the translation of SPARQL queries to the query languages of the engines on these triplestores rely also adds extra costs.

8.2. Spark based triplestores

Spark's solution is based on storing processed data and intermediate results in main memories of computing nodes and keeping a history of the computations for recovering lost data in case of failures. This let Spark enhances speed since the switching to disk is not frequent as it is in the case for Hadoop MapReduce executions. At the base of computation, Spark uses the so called Resilient Distributed Datasets (RDDs) which are collections of data partitioned into chunks distributed on the computing nodes and kept as much as possible in main memory. Such RDDs are represented as Java objects.

Spark also provides a module for SQL. SQL querying is done on RDDs which enables fast querying through the parallel computation offered by Spark across the nodes while benefiting from the use of memory to store RDDs. SQL querying on external data like Hive data is also done by loading such data into Spark RDDs.

Spark is used by the triplestores SPARQLGX [58], S2RDF [59], SPARQL-Spark [60], PRoST [61], TripleRush [62] and Presto-RDF [63].

The triplestore S2RDF (“SPARQL on Spark for RDF”) tries to minimize times of query processing by reducing the amounts of data to keep in memory. For this, it uses a schema for RDF data that extends the predicate-oriented partitioning schema already presented in subsection 6.1.1.3 with additional pre-computed tables. The main idea behind this schema is to reduce the size of data to be loaded into memory when dealing with joins within the queries to be processed. This has the advantage of avoiding input-output hard disk operations since spark keeps data in memory for programs execution. For two distinct predicates tables T1 and T2, S2RDF pre-computes and stores into HDFDS three semi-join tables of those (s,o) pairs of T1 for which, respectively, s is a subject in the second, o is a subject in T2 and s is an object in T2. A limitation of S2RDF is the need for additional functionalities for the automatic launching of an efficient updating of the semi-join tables each time a deletion of some existing triples or an insertion of new ones happen.

With regards to the aforementioned characteristics of Spark based triplestores, such triplestores have the advantage over Hadoop ones of largely reducing RDF data processing costs since the input-output operations are largely reduced due to the fact that RDF data and intermediary data is mainly kept partitioned in memories of processing nodes during the processing stages.

8.3. Flink based triplestores

Flink is natively developed for data streaming and offers massive real time streaming functionalities. It also offers APIs for data mining operations on streams. Flink can be considered as a Big Data engine for event streaming while Spark can be considered as a Big Data engine for micro-batch streaming.

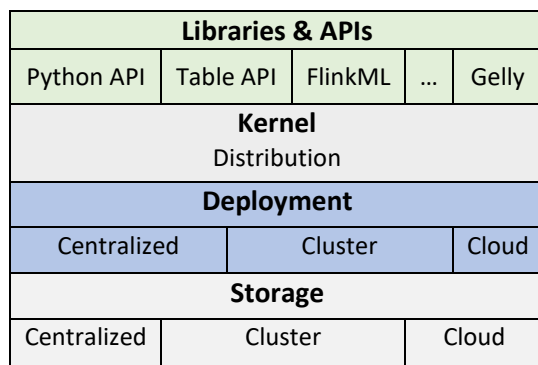

Figure 12: Flink architecture

Flink is developed in Java and Scala and provides an API for the processing of graphs called Gelly. Components of Flink are presented in Figure 12.

FLINKer [64] is an example of a triplestore that is based on Flink and provides therefore RDF data streaming. In FLINKer, Gelly graphs are built from RDF triples and then loaded in the Flink system to be handled. This graph representation is a strong positive point of FLINKer since it allows easy graph partitioning and distribution of data processing among nodes. For RDF data querying FLINKer uses Flink data processing operators on Gelly

graphs to generate query optimization plans based on Flink parallelization contract programming approach (PACT) for a parallel execution.

Though these advantages of FLINKer, it still needs adding some functionality for more user involvement with regards to possible extensions of FLINKer with APIs for data representation based on Gelly graphs and for data analytics purposes. Also, FLINKer lacks elements for transaction management.

9. Stores for Constrained Devices

Micro computing has made it possible to integrate programmable modules with memories for data storage in devices with reduced capacity. Various devices with such modules have been developed in recent years for various applications (edge devices, sensors, etc.). The integration of RDF processing systems has also become possible for such small peripherals despite their limited memory capacity. In the category of triplestores for constrained devices we have μ RDF store [65], RDF4Led [66] and Wiselib [67].

The μ RDF store was developed with the aim to make the exchange and treatment of RDF data possible in the world of “internet-of-things” (IoT). It was tested for micro-controllers with memories ranging from 8 to 64 kB and with an internet connection. The tests include the storage of RDF data as well as SPARQL querying using basic SPARQL constructs.

RDF4Led, on the contrary, addresses RDF data exchange for lightweight edge devices. Such devices are largely common in IoT as well as in Cloud computing. The RDF4Led built-in system comprises a physical storage with an indexing strategy of triples, an intermediary buffering unit and a query engine. Efficiency of RDF4Led has been proven for devices with some hundreds of Mbytes in main memory and with a storage capacity of 16 GBytes.

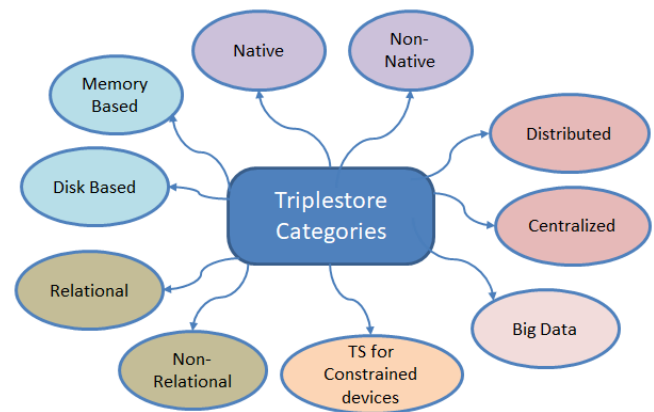

Figure 13: Main Categories of Triplestores

10. Comparison with Related Works

We notice that most existing works concentrate on a specific type of triplestores for reviewing or categorizing triplestores principally with limited characteristics or for comparing query processing times. We principally mention the works in [68] for the case of relational stores, in [69] for NoSQL stores, in [70] for P2P stores and in [71] for Big Data stores.

Contrary to these works, our approach comes with a consistent and detailed categorization with a focus on the storage and query processing characteristics. Figure 13 presents the main categories. As already mentioned, some of existing triplestores can be part of several categories.

For other issues related to detailed comparison criteria for RDF stores we refer to our work in [72].

11. Conclusion

The enormous acceptance of RDF in many fields has led to the development of various triplestores for the management of RDF data with each triplestore exhibiting its own characteristics. The variety of triplestores is of course a result of the variety of application use cases and of the various characteristics of data to be handled. Such characteristics are mainly related to data variety, to the volumes of data and to the data management tools and technologies. In this work we gave an extensive categorization of existing triplestores while identifying, for each established category its associated key features that make it to be treated separately, and presenting its underlying RDF data processing capabilities. We mainly focused on the data processing techniques used by the systems of each category as well as the modes of their deployment for the processing of RDF data and queries. The list of the different categories of triplestores is indeed established according to destination machines if they are for constrained devices, for desktops or for clusters, as well as depending on the technologies on which they are based: relational, non-relational, Cloud, P2P or Big Data. The categorization is also illustrated by reviewing within each category its representative RDF triplestores while highlighting advantages and disadvantages of the technology on which they are based in the context of RDF data characteristics and giving some suggestions for possible extensions.

With the given categorization, users will be able to identify the best suited triplestores for their use cases. Also, triplestores designers will be able to adequately focus on the relevant features to consider for the challenging task of design and development of RDF stores or to identify possible extensions of existing stores dependently on the targeted data management types and the tools at hand.

Multivariate Analysis

ABSTRACT

Forecasting the gold price movement's volatility has essential applications in areas such as risk management, options pricing, and asset allocation. The multivariate model is expected to generate more accurate forecasts than univariate models in time series data like gold prices. Multivariate analysis is based on observation and analysis of more than one statistical variable at a time. This paper mainly builds a multivariate prediction model based on Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) model to analyze and forecast the price of the gold commodity. In addition, the prediction model is optimized with a Cross-Validated Grid Search to find the optimum hyperparameter. The empirical results show that the proposed Timeseries Prediction model has an excellent accuracy in prediction, that proven by the lowest Mean Absolute Percentage Error (MAPE) and Root Mean Square Error (RMSE). Overall, in more than three years data period, LSTM has high accuracy, but for under three years period, GRU does better. This research aims to find a promising methodology for gold price forecasting with high accuracy.

1. Introduction

In today's economy, gold is becoming an essential financial commodity. Gold has become the underlying value for many reasons. Security is the first one. Gold is a robust investment instrument, capable of preserving its liquidity even in crises such as political turbulence [1] and the COVID-19 pandemic [2]. The second is that when they have had problems with their balance of payments, many nations have repeatedly used gold collateral against loans. The final reason is that for coping with inflation, gold will serve as a guide. Research on gold's value is fundamental because gold prices can quite directly reflect the economy's market expectations. Gold value prediction is a difficult task, primarily because of the unusual shifts in economic patterns and, on the other hand, insufficient knowledge. ARIMA is a classical approach focused on the estimation of statistical time series and a prediction model for univariate time series. The critical drawback of ARIMA is the model's pre-assumed linear shape. With the rise of machine learning, artificial neural networks in time series forecasting have been widely studied and used.

Recurrent neural networks (RNN) [3] are often seen as the most efficient time series prediction method. RNN is a subset of artificial neural networks in which nodes are connected in a loop, and the internal state of the network can exhibit dynamic timing

behavior. However, as the length of the processing time series increases, problems such as gradient disappearance often occur during the training of RNNs using conventional activation functions, such as tanh or sigmoid functions, limiting the prediction accuracy of the RNN. According to Ahmed & Bahador, the highest precision RNN is LSTM (Long Short Term Memory) Neural Network[4]. LSTM has an outstanding efficiency in natural language processing, while this model can also solve long-term dependencies very well. Since problems with long-term dependencies exist in the prediction of time series, researchers are trying to use LSTM to solve problems with time series, such as forecasting of foreign exchange [5, 6], traffic flow analysis [7, 8], and gold ETF[9]. The Gated Recurrent Unit is another type of RNN (GRU). GRU is an RNN-based network, a form of gated RNNs, which largely mitigates the gradient vanishing problem of RNNs through gating mechanism and make the structure simpler while maintaining the effect of LSTM [10]. This research's main objective is to study RNN forecasting methods that offer the best predictions for multivariate gold price prediction concerning lower forecast errors and higher accuracy of forecasts. Research on multivariate analysis has multiple features to determine the predicted value.

The dataset for the prediction model consists of eight features after feature selection is conducted :

1. Gold Price in IDR

8. NASDAQ Composite Index

Historical data on this paper is gathered from the World Gold Council website (gold.org) and investing.com. Data is collected in an interval of 20 years, start from 2001 to 2020. The author split the dataset into 70% training data and 30% testing data. The validation data is a subset of training data, and the length is 10% of the total data. The validation data is based on 20 years dataset.

2. Literature Review

2.1. Data Preprocessing

Pre-processing is a method to develop data to form good shape for data training. Data pre-processing is a fundamental stage of the machine learning application, which has been reported to significantly impact the performances of machine learning methods [11]. Data pre-processing techniques include reduction, projection, and missing data techniques (MDTs). Data reduction decreases the data size via, for example, feature selection (FS) or dimension reduction [12].

2.2. Grid Search

Grid search is a process that attempts each hyper-parameter combination extensively and selects the best as the optimal hyper-parameters[13]. The grid search method is theoretically capable of finding optimal solutions. However, it suffers from severe limitations in the following aspects. It can not provide optimal solutions within a sufficient reach with limited computational resources. However, Grid search specializes in addressing discrete hyper-parameters [14].

2.3. Feature Selection

Feature selection is referred to as obtaining a subset from an original feature set by selecting the dataset's relevant features according to the unique feature selection criteria [15]. Feature selection has a vital role in compressing the data processing size, where the redundant and irrelevant characteristics are eliminated. Feature selection techniques can pre-process learning algorithms, and proper feature selection results can improve learning accuracy, reduce learning time, and simplify learning results [16].

2.4. Long Short Term Memory (LSTM)

Long short-term memory (LSTM) is an altered version of RNN proposed to learn long-range dependencies across time-varying patterns [17]. Generally, LSTM is a second-order recurrent neural network that solves the vanishing and exploding gradients issue by replacing RNN simple units with the memory blocks in a recurrent hidden layer. A memory cell is a complex processing unit in LSTM with many units shown in Figure 1.

It comprises one or many memory cells, adaptive multiplicative gating units (input, output, and forget), and a self-recurrent connection with a fixed weight of 1.0. It serves as a short-term memory with control from adaptive multiplicative gating units. The input and output flow of a cell activation of a memory cell is controlled by input and output gate, respectively. Forget gate

was included in memory cell [18] that helps to forget or reset their previous state information when it is inappropriate.

(a) Long Short Term Memory Unit.
i: Input Gate, f: Forget Gate, o: Output Gate.

Figure 1: LSTM Cell Unit: Image Source [19]

2.5. Gated Recurrent Unit (GRU)

The GRU is a simpler derivative of the LSTM network, and in some cases, both produce comparative results. Although there are major similarities in architecture for the purpose of solving vanishing gradient problems, there are several differences. The structure of a GRU module is shown in Figure 2.

(b) Gated Recurrent Unit.
z: update Gate, r: Reset Gate.

Figure 2: GRU Cell Unit: Image Source [19]

The GRU cell does not have a separate memory cell-like LSTM cell architecture, according to [20]. In addition to having three gating layers like LSTM in each module, the GRU network only has two gating layers, a reset gate, and an update gate. The reset gate decides how much information to forget from the previous memory. The update gate acts similar to the forget and input gate of an LSTM cell. It decides how much information from previous memory can be passed along to the future.

3. Methodology

3.1. Data Collection and Preprocessing

This research collects gold price values on a daily basis. The collected data has twelve features: gold price in Indonesian Rupiah (IDR), gold price in US Dollar (USD), gold price in Euro (Euro), gold price in Pound sterling (GBP), gold price in Chinese Renminbi (RMB), gold to silver ratio, Japanese Stock Market Index (Nikkei 225), Indonesian Stock Composite Index (IHSG), Shanghai Hang Seng Index (Hang Seng), Nasdaq Index (Nasdaq), US Dollar and Indonesian Rupiah currency pair (USD/IDR), Australian Dollar and US Dollar currency pair (AUD/USD). The price and supporting data were collected from January 1, 2001, to 09:00 on December 31, 2020, through the World Gold Council (gold.org) and investing.com.

Table 1: Example of the collected raw gold price data

Date	IDR	USD	Euro	GBP	RMB	Gold / Silver	Nikkei 225	IHSG	Hang Seng	Nasdaq	USD/IDR	AUD/USD
Dec 22 2020	26664206.89	1877.1	1542.6	1409.6	12290.9	73.41	26436.39	6023.29	26119.25	12717.56	14145.0	0.7521

3.2. Feature Selection

Feature selection is implemented by calculating Pearson's Correlation Coefficient. The correlation value can be seen in Table 2, and the visualization of feature correlation could be inferred in Figure 3.

The defined threshold for features correlation is 0.75. All features that have correlation coefficient values below the threshold would be removed, and all features above that point will

be used as selected features. An example of pre-processed data can be seen in Table 3.

3.3. Model Training and Validation

The prediction in this work is to utilize the LSTM model to forecast the gold price. As a modified version of the recurrent neural network model, the LSTM model [21] defines whether the weight value is maintained by adding cell states in an LSTM cell.

Figure 3: Pearson Correlation Matrix of All Features

The LSTM model can accept an arbitrary length of inputs, and it can be implemented flexibly and in various ways as required. The state obtained from an LSTM cell is used as input to the next LSTM cell, so the state of an LSTM cell affects the operation of the subsequent cells. The LSTM predictive model has the capability to remove or add information to the LSTM cell state.

The information that enters the cell is controlled by gates, a component that represents a way to save or forget information through the LSTM cell unit.

In order to enrich and benchmark the proposed LSTM model, this research also develops a GRU prediction model. GRU model is similar to LSTM and is known to have good forecasting

performance for a shorter time period. The same model tuning process for the GRU prediction model was also performed for the purpose of fairness. The overall training and tuning process is summarized in Figure 4.

3.4. Hyperparameter Tuning

Hyperparameter optimization is an essential step in the implementation of any machine learning model [22]. This optimization process includes regularly modifying the model's hyperparameter values to minimize the testing error. Based on research, kernel initializer and batch size need to optimize for better accuracy [22]. Meanwhile, the author proposed dropout rate, neuron units, and learning optimizer [23]. Research from Google Brain Scientist studied the relation between two hyperparameters, batch size, and learning rate [24]. When the learning rate is decay, random fluctuation appears in the SGD dynamics. Instead of decaying the learning rate, that research increase the batch size. That strategy achieves near-identical model performance on the test set with the same number of training epochs but significantly fewer parameter updates. However, when the batch size is large, this often causes instabilities during the early stages of training. In consequence, the optimum batch size value must be decided for the best prediction result.

Furthermore, the dropout rate indicates the fraction of the hidden units to be dropped to transform the recurrent state in the LSTM layer. Finally, the optimization type designates the optimization algorithm to tune the internal model parameters to minimize the cross-entropy loss function [23]. This paper combines two prior research and choose the batch size, kernel initializer, dropout rate, neuron units, and learning optimizer based on the references. The proposed hyperparameter candidates for LSTM could be shown in Table 4 and GRU in Table 5.

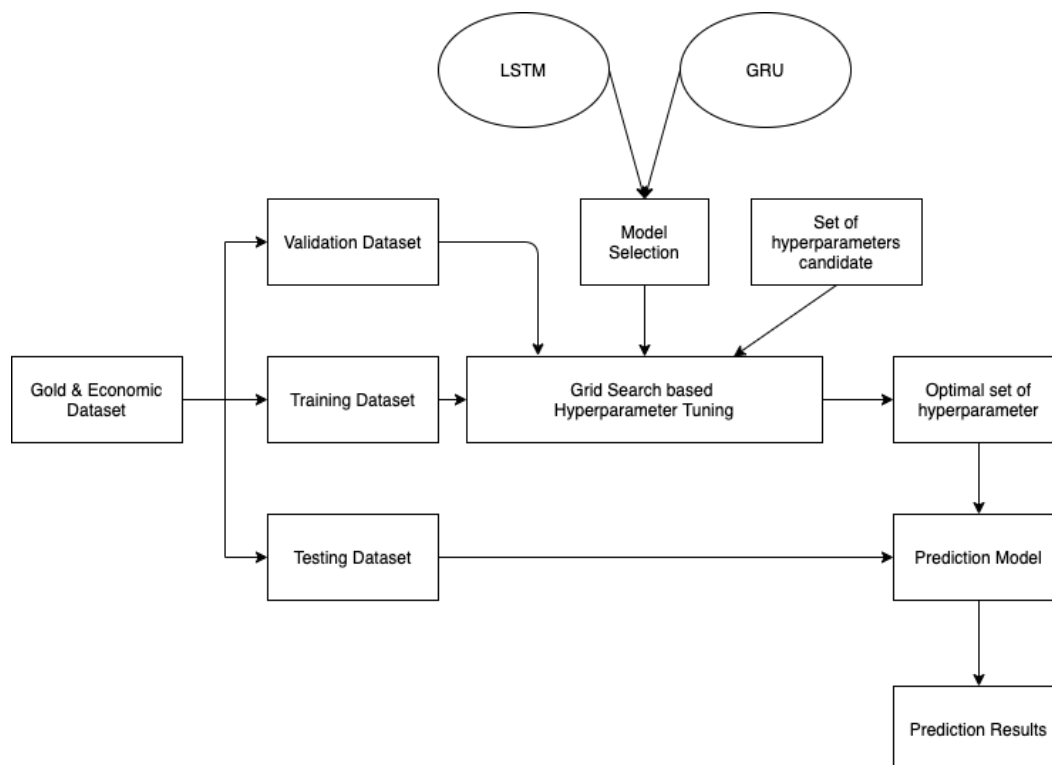

Figure 4: Prediction model training and tuning process with grid search

The kernel initializer represents the strategy for initializing the LSTM and Dense layers weight values. The activation type represents the activation function that produces non-linear and limited output signals inside the LSTM, Dense I, and II layers.

Table 4: Candidate and optimal sets of hyper-parameters for LSTM

Hyper-parameter name	Hyper-parameter values candidate	Optimal Hyper-parameter values
Kernel Initializer	lecun_uniform, zero, ones, glorot_normal, glorot_uniform, he_normal, he_uniform, uniform, normal, orthogonal, constant, random_normal, random_uniform	ones
Batch Size	16, 32, 64, 128, 256, 512, 1024	16
Dropout Rate	0.0, 0.2, 0.3, 0.4	0.0
Neuron Units	32, 64, 128	128
Learning Optimizer	SGD, RMSProp, Adagrad, Adam	Adam

Table 5 : Candidate and optimal sets of hyper-parameters for GRU

Hyper-parameter name	Hyper-parameter values candidate	Optimal Hyper-parameter values
Kernel Initializer	lecun_uniform, zero, ones, glorot_normal, glorot_uniform, he_normal, he_uniform, uniform, normal, orthogonal, constant, random_normal, random_uniform	ones
Batch Size	16, 32, 64, 128, 256, 512, 1024	64
Dropout Rate	0.0, 0.2, 0.3, 0.4	0.0
Neuron Units	32, 64, 128	64
Learning Optimizer	SGD, RMSProp, Adagrad, Adam	Adam

3.5. Model Evaluation

In order to measure the error of the prediction model for the time series problem, the researcher utilizes Root Mean Squared Error (RMSE) and Mean Absolute Percentage Error (MAPE).

3.5.1. Root Mean Squared Error

$$RMSE = \sqrt{\frac{1}{n} \sum_{t=1}^n e_t^2} \quad (1)$$

Root Mean Squared Error (RMSE) is derived from Mean Squared Error. It represents the average difference between predicted and real value. The formula of RMSE can be seen in (1). RMSE is common practice to calculate the accuracy of the prediction model.

3.5.2. Mean Absolute Percentage Error

$$MAPE = \frac{100\%}{n} \sum_{t=1}^n \left| \frac{e_t}{y_t} \right| \quad (2)$$

Mean Absolute Percentage Error (MAPE) calculates the average delta between predicted and real value and represent in percentage. The formula of MAPE can be seen in (2).

4. Results and Analysis

4.1. Prediction Result for Simple LSTM and GRU

Table 6 shows the training result of the proposed methods and some state of arts who have studied a forecasting gold price model. Inspire by that state of arts, the author utilizes RMSE and MAPE to evaluate the proposed model. The proposed models have 25 epochs, 32 batch sizes, a 0.2 dropout rate value, 32 neuron units, a uniform kernel initializer, and RMSProps Learning Optimizer. Derive from Table 6 can be known that GRU has lower error for three months until three years than LSTM. For the period above three years, LSTM has a lower error rate.

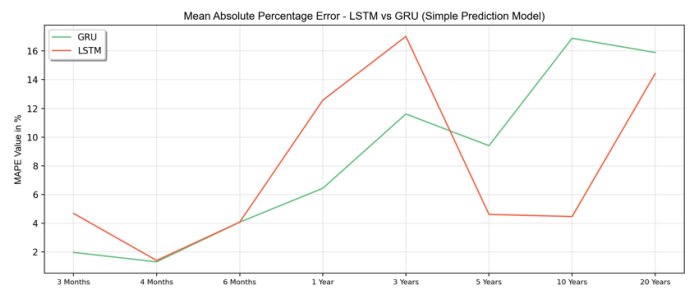

Figure 6: MAPE Value of Simple Prediction Model

Table 6: Forecasting Result with Simple Prediction Model

Simple Prediction Model				
Interval	RMSE		MAPE	
	LSTM	GRU	LSTM	GRU
3 Months	1,305,470.42	628,984.55	4.68 %	1.96 %
4 Months	476,750.72	460,679.94	1.40 %	1.30 %
6 Months	1,260,382.60	1,262,250.99	4.07 %	4.07 %
1 Year	3,529,122.74	1,813,811.23	12.57 %	6.43 %
3 Years	4,528,491.45	3,043,471.50	17.02 %	11.61 %
5 Years	1,012,206.71	2,164,846.99	4.61 %	9.40 %
10 Years	983,174.32	3,276,504.50	4.46 %	16.89 %
20 Years	2,784,692.49	3,055,371.13	14.43 %	15.90 %

As presented in Figure 5, the value of RMSE for both LSTM and GRU is decreased over time. However, GRU has a lower error rate in intervals until three years, while LSTM is more accurate in the above three years intervals. RMSE indicates the average value of the difference between the predicted and real value.

Figure 5: RMSE Value of Simple Prediction Model

As presented in Figure 6, the value of MAPE for both LSTM and GRU is decreased over time. However, GRU has a lower error rate in intervals until three years, while LSTM is more accurate in the above three years intervals. MAPE indicates the percentage of the overall delta between predicted and real value.

Figure 7: LSTM Prediction for 3 Years Training Data

LSTM prediction model for three years period is accurate in train prediction but moderately inaccurate in test prediction, as seen in Figure 7. Averagely, it has around 4 million rupiah difference between predicted and real value that represented by RMSE. The reason is LSTM needs a large dataset to predict accurately.

Figure 8: GRU Prediction for 3 Years Training Data

On the contrary, for three years period, the GRU model gives good accuracy. Averagely, it has around 3 million rupiah difference between predicted and real value that represented by RMSE. It indicates that, for intervals up to 3 years, the GRU model is preferable.

Figure 9: LSTM Prediction for 20 Years Training Data

Figure 9 shown the LSTM prediction model for twenty years period. The model has pretty good accuracy. Averagely, it has around 2.7 million rupiah difference between predicted and real value that represented by RMSE.

Figure 10: GRU Prediction for 20 Years Training Data

For twenty years period, the GRU model slightly less accurate than the LSTM model. Averagely, it has around 3 million rupiah difference between predicted and real value that represented by RMSE. It indicates that, for intervals up to 20 years, it is better to use the LSTM model. According to data in Table 6, LSTM accuracy increase over time, while GRU accuracy is great for a short time period but has lower accuracy for a long period. However, the accuracy can be improved by applying Hyperparameter Tuning using Cross Validated Grid Search.

Table 7: Forecasting Result with Grid Search Optimized Prediction Model

Grid Search Optimized Prediction Model				
Interval	RMSE		MAPE	
	LSTM	GRU	LSTM	GRU
3 Months	905,316.59	1,878,634.45	3.25 %	7.12 %
4 Months	379,823.43	1,486,398.71	0.97 %	5.52 %
6 Months	336,076.94	1,348,307.28	0.87 %	4.82 %
1 Year	415,606.27	384,696.30	1.06 %	1.00 %
3 Years	354,942.67	343,101.59	0.96 %	0.94 %
5 Years	314,599.02	278,038.93	0.90 %	0.77 %
10 Years	227,230.62	232,294.05	0.74 %	0.76 %
20 Years	213,036.85	216,012.48	0.72 %	0.73 %

4.2. Prediction Result for Optimized LSTM and GRU

Model Optimization for LSTM and GRU conducted by applying Hyperparameter tuning using Cross Validated Grid Search. Grid Search tries every value on the hyperparameter candidate that is stated in Table 4 for LSTM and Table 5 for GRU. After Grid Search was conducted, the best result for each iteration becomes hyperparameter value on Optimized LSTM and GRU Model. The optimized LSTM models have 25 epochs, 16 batch sizes, a 0 dropout rate value, 128 neuron units, "ones" kernel initializer, and utilize ADAM optimizer. The training result of optimized LSTM and GRU using grid search based hyperparameter tuning can be seen in Table 7. Derive from Table 7, and it can be known that for three months until three years, GRU has lower error than LSTM. For the period above three years, LSTM has a lower error rate. Results accuracy of the optimized model can be seen in Figure 11 for RMSE and Figure 12 for MAPE.

Figure 11: RMSE Value of Optimized Prediction Model

Figure 11 shows that in the optimized model, LSTM has a better RMSE score than GRU in almost all time intervals. GRU model slightly performs better in time interval one year until three years.

Figure 12: MAPE Value of Optimized Prediction Model

Figure 12 also shows a similar result with RMSE. MAPE score in the optimized model, LSTM has better accuracy than GRU in almost all time intervals. GRU model also slightly performs better in time interval one year until three years. It indicates that, for the model that is optimized with grid search, LSTM has better accuracy than the GRU predicted model.

Forecasting gold price for three years interval using optimized LSTM and GRU model has a similar result. It has a 354942.67 RMSE value for LSTM and 343101.59 for GRU. In MAPE measurement, LSTM has 0.96 error, while GRU has 0.96 error. It indicates that for interval three years, GRU Model is slightly more accurate.

Figure 13: Optimized LSTM Prediction for 3 Years Training Data

Figure 14: Optimized GRU Prediction for 3 Years Training Data

Figure 15: Optimized LSTM Prediction for 20 Years Training Data

Figure 16: Optimized GRU Prediction for 20 Years Training Data

Forecasting gold price for twenty years intervals using optimized LSTM and GRU model also has a similar result. It has a 213036.85 RMSE value for LSTM and 216012.48 for GRU. In MAPE measurement, LSTM has 0.72 error, while GRU has 0.73 error. It indicates that for the interval of twenty years, LSTM Model is slightly more accurate. Summary prediction result accuracy for all time intervals can be seen in Table 8.

5. Conclusion

According to the training, validation, and hyperparameter tuning, the best model to use in gold price forecasting problems for time intervals under three years period is GRU. On the other hand, for time intervals above three years, LSTM is shown higher accuracy. That is shown by RMSE and MAPE Score. Grid Search based Hyperparameter tuning is proven to increase LSTM accuracy significantly by decreasing its error. Table 8 shows that

Table 8: Prediction Model Forecasting Result Summary

Interval	RMSE						MAPE					
	LSTM			GRU			LSTM			GRU		
	Simple	Optimized	Delta	Simple	Optimized	Delta	Simple	Optimized	Delta	Simple	Optimized	Delta
3 Months	1,305,470.42	905,316.59	31%	628,984.55	1,878,634.45	-199%	4.68%	3.25%	1.43%	1.96%	7.12%	-5.16%
4 Months	476,750.72	379,823.43	20%	460,679.94	1,486,398.71	-223%	1.40%	0.97%	0.43%	1.30%	5.52%	-4.22%
6 Months	1,260,382.60	336,076.94	73%	1,262,250.99	1,348,307.28	-7%	4.07%	0.87%	3.2%	4.07%	4.82%	-0.75%
1 Year	3,529,122.74	415,606.27	88%	1,813,811.23	384,696.30	79%	12.57%	1.06%	11.51%	6.43%	1.00%	5.43%
3 Years	4,528,491.45	354,942.67	92%	3,043,471.50	343,101.59	89%	17.02%	0.96%	16.06%	11.61%	0.94%	10.67%
5 Years	1,012,206.71	314,599.02	69%	2,164,846.99	278,038.93	87%	4.61%	0.90%	3.71%	9.40%	0.77%	8.63%
10 Years	983,174.32	227,230.62	77%	3,276,504.50	232,294.05	93%	4.46%	0.74%	3.72%	16.89%	0.76%	16.13%
20 Years	2,784,692.49	213,036.85	92%	3,055,371.13	216,012.48	93%	14.43%	0.72%	13.71%	15.90%	0.73%	15.17%
Average			68%	Average			Average			Average		
							6,72%			5,74%		

grid search can averagely decrease 68% RMSE and decrease 6,72 MAPE score. It also improves GRU Model, averagely decreases RMSE by 2%, and decreases 5,74 MAPE score. From that information, this research shows that hyperparameter tuning is more effective in optimizing LSTM Model than GRU Model for this research, *gold price prediction problem*. For future research, it is good to apply metaheuristic methods, such as Ant Colony Optimization, Genetic Algorithm, or Chaotic Metaheuristic, to conduct hyperparameter tuning with better performance.

ABSTRACT

Consideration of building energy performance in the early stage of the design process is very important to help minimizing energy consumed by the built environment. Therefore, help in minimizing energy crisis problem. Optimization of building form and orientation at the early stage of the design process can save a significant amount of energy consumed by the building. This paper proposes an annual thermal energy performance-based form making (EPBFM) method that generates numerous design configurations and tests their annual thermal energy performance till it reaches an optimal solution. The proposed workflow uses 3d parametric modeling program, energy simulation program, and genetic algorithm. A case study of an open plan office building is used to evaluate the proposed workflow in three different cities with different climates, Cairo, London, and Chicago. Building's contexts were not considered in order to highlight the change of the building form and orientation caused due to the change in climate conditions. Then, Scatterplots were developed to test the impact of each dynamic parameter on thermal energy use intensity (EUI). Compared to the initial square shaped building, optimization results showed that thermal EUI decreased by 22.76%, 29.7%, and 19.2% in Cairo, London, and Chicago, respectively. Manipulation of building area along one axis and each floor area along the other axis proved to have the highest positive impact in decreasing thermal EUI.

1. Introduction

The built environment continues to magnify the energy crisis problem. HVAC systems are responsible for a significant percentage of the total energy used in buildings [1]. Building form and orientation decided at the early stages of the design process have the highest percentage of energy saving potential of a building [2]. However, there is still a lack in studies that consider manipulation of building form and orientation for energy performance at the early stage of the design process.

Through reviewing journal articles that optimize building form, and/or orientation for energy performance, we found that some research focused on the form representation without considering a certain type of building program. For example, [3], and [4] optimized a single zone cubic form to generate irregular complex

forms through the manipulation of building points. The research highlighted the importance of generating complex forms to enhance building energy performance, as the basic forms such as cube and cuboid are too strict. The purpose was to minimize energy use in Philadelphia in the first study, and in three different climates, namely hot, cold, and temperate in the second one. In [5], the authors presented a form representation of a single zone free form that was optimized for thermal performance in fourteen different cities with different local climate condition.

There are also studies that were performed considering different types of buildings. Example of the research performed on office buildings, [6] optimized rectangular shaped five-floor office building in Milan, North Italy. The research manipulated the two dimensions of the whole building, and its orientation along with envelope and HVAC operation parameters. In [7], the authors optimized a rectangular shaped small single-story office building

<https://dx.doi.org/10.25046/aj060228>

with a pitched roof in Miami, Atlanta, and Chicago. The form dynamic parameters manipulated were the building depth and the roof ridge. In [8], the authors optimized an open plan rectangular office building consists of three floors in Los Angeles, Helsinki, Mexico City, and New York City. The form dynamic parameters were the addition of corners to the whole building, and the addition or elimination of a courtyard. Orientation was also manipulated in all cases except for Los Angeles. Examples of the research performed on residential buildings, [2] optimized two floor building with four rooms in each floor in Chicago, Phoenix, and Oporto. In [9,10], the authors considered Lisbon, Portugal. In [11], the authors generated twelve alternatives of a single level, and a two-level houses in Coimbra, Portugal. In [12], the authors optimized two slab buildings attached to a corner tower in four warm temperate climate cities in Argentina, and Spain. In [13], the authors optimized rectangular multi-apartment house with a central staircase in Budapest, Hungary. Examples of the research performed on school buildings, [14] optimized one class room unit and its' open corridor, one class room unit and its' enclosed corridor, two class rooms and their corridor. In [15], the authors optimized ceiling height and envelope of a single classroom unit. Examples of research performed on sports buildings are found in [16], and [17]. In [12], the authors performed research on rural tourism buildings and considered four warm temperate climate cities in Argentina, and Spain. Many studies that optimized building envelope for energy performance exist but studies that optimize building form for energy performance are still limited and need more contributions to include varieties of form representation, and different cities with different local climate conditions.

This paper develops a thermal EPBFM optimization method for a three-floor open plan office building in Cairo, London, and Chicago. The building is square shaped in its initial state, and each of the three floors changes its shape to squares and rectangles with different sizes during optimization. The surroundings were not considered to be able to understand the change that occur to the building form and orientation due to the change in local climate conditions. This method allows for the optimization of building form and orientation parameters using genetic algorithm to enhance thermal energy performance of the building. After the optimization, numerous alternative design configurations are generated and ordered in reference to their thermal energy performance.

2. Methodology

The EPBFM optimization method was applied to an open office building in three different cities with different climate conditions, Cairo (Arid climate), London (Temperate climate), and Chicago (Cold climate). The surroundings were not considered to be able to understand the change that occur to the building form and orientation due to the change in local climate conditions. It is assumed that the initial building form is a three-floor squared building where each floor represents an open office plan with 3m height. The initial building is 10 * 10 m, with total built up area 300 m², and total volume 1296 m³(figure 1.).

The usage of Grasshopper along with a 3d program in the early stage of the design process is very important because non-programmers can deal with it easily [18]. Grasshopper [19] with its user-friendly graphical user interface (GUI) is used to develop the thermal EPBFM optimization method that can evaluate the thermal

energy performance of numerous architectural form design alternatives in the early stage of the design process. This workflow optimizes the form and orientation of the initial squared building form to generate diversity of building design configurations and test their thermal performance. The initial form is then used as the base case to compare results of new generated forms to it. EnergyPlus is used to perform the simulation, and each floor is considered as one thermal zone (open office space) in the thermal energy simulation. The workflow consists of the following phases:

Figure 1: Initial squared building form, with the north direction presented in the bottom right. (north-west view)

2.1. Model architectural building form

Rhinoceros 6 [20] and its plug-in software Grasshopper were used to model the architectural building form and to assign its different dynamic and static parameters. The same building form and orientation dynamic parameters were assigned to each of the three cases. While building envelope parameters such as external wall and roof materials were fixed with specific values for each of the three climates to suit specific local climate conditions. Table.1 and 2 represents building static parameters. Table 1 represents the external wall, window, and roof name and U- values, while table 2 represents the external walls, and roof materials.

Table 1: Building parameters fixed within each climate.

After modeling the building form and deciding its dynamic parameters (genes). The number sliders of the chosen dynamic parameters are connected to the genetic algorithm optimizer that changes sliders values in each iteration. The building form and orientation dynamic parameters are explained in Table.3 with their number, values, and values' units. The height of each floor is allowed to have two values only 3m, or 6m. The building is allowed to expand its area gradually in the east-west direction. In addition, each floor is allowed to expand its area gradually in the north-south direction. Eleven values were assigned to both expansion dynamic parameter. These values start with the base case value (1 %) which is equal to 10m and ends with 2% which mean that the length of the building is multiplied by two to become 20 m. Finally, the whole building is allowed to rotate gradually anti-clock wise with 21 values that starts with 0 radians and ends with 2 radians to avoid repetition of forms as the building is symmetrical on both north-south, and east-west axes.

Table 3: Form and orientation dynamic parameters for the three climate zones. Table presents north-west bird eye perspective

Form dynamic parameters	No. of parameters	Attributes for each parameter. (unit)
Building height 	1	3 (base case), and 6. (Meters)
Building expansion 	1	1(base case),1.1,1.2, 1.3,1.4,1.5,1.6,1.7,1.8, 1.9, and 2. (%)

Floor expansion 	3	1(base case),1.1, 1.2,1.3,1.4,1.5,1.6,1.7,1.8,1.9 , and 2. (%)
Building rotation in the anti-clock direction.	1	0 (base case), 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1, 1.1,1.2,1.3,1.4,1.5, 1.6,1.7,1.8,1.9, and 2. (Raadians.)

2.2. Simulation and optimization

In [21], the authors plug-ins for Grasshopper are used to add physical properties of building envelopes, to connect to energy simulation engine EnergyPlus, and to insert natural conditions found in the EnergyPlus Weather file (.epw) for each of the three chosen cities. The thermal energy outputs represent annual heating and cooling loads. In this paper each of the three building floors were considered as a single open office thermal zone. It is worth mentioning that the default program assigned to buildings by ladybug and honeybee is office building, and the default zoning assigned to spaces is open office.

Optimization allows for the exploration of a large number of design alternatives to find the minimum or maximum value of an objective function when reaching the best value for dynamic parameters [7]. Octopus is a grasshopper genetic algorithm plug-in based on SPEA-2 and HypE algorithm that can be used to run single objective optimization process while involving genetic diversity as a second objective [22]. Octopus is used to perform single objective optimization to minimize annual thermal EUI. Octopus was stopped after performing 6 generations for each case starting from zero to five. Thermal EUI of the building was used to calculate the annual thermal energy consumed per unit area as a result of the changing of the area of the building during optimization. Lastly, Octopus user interface is used to compare results presented in the graph.

In this paper, the evaluation objective function is to minimize annual thermal EUI, in addition to promoting genetic diversity. Percentages of reduction or increase of total thermal EUI load per unit area of new generated design configurations in comparison to the base case were calculated using the following equation (Eq. (1)):

$$F(x) \text{ total thermal load} = 100 (1 - f(g)/f(i)) \quad (1)$$

where F(x) is the value that calculates the percentage of reduction or increase in the objective function (annual thermal EUI). And, f(g) represents the simulation result of each of the new generated design configurations and f(i) is the simulation result of the initial base case. Positive results indicate the reduction of annual thermal EUI, and negative results indicate the increase in annual thermal EUI.

3. Results and Discussion

The results demonstrated that the proposed EPBFM method is capable of enhancing thermal energy performance of building form in the hot, cold, and temperate climate zones. EPBFM method also provides diversity of design configurations with better performance

for designers to choose the best configuration that suits project other needs. This was achieved using just one initial form with the same form and orientation dynamic parameters. Thermal energy use intensity (EUI) savings were 22.76% for Cairo, 29.7% for London, and 19.2 for Chicago in comparison to the initial square shaped building form. This workflow helps architects to include energy assessment at the early stage of the design process using a friendly GUI to generate and test numerous alternative design configurations, that they cannot design and test without the help of a computational generative design tool. In addition, the solutions found in the Octopus user interface help architects to understand the role of different dynamic parameters and their assigned values in enhancing or worsening the thermal energy performance. The proposed method proves to be beneficial to contribute to the research concerned with enhancing energy performance in the built environment. And could be further developed through the addition of different types of dynamic parameters and/ or the application to other climate zones.

For each case of the three cities, the pareto front configurations were chosen to present the optimal design configuration that has the lowest thermal EUI and the worst design configuration that has the highest thermal EUI. In addition, to presenting some design configurations in between them. Figures 2,3, and 4 shows the three graphs in the Octopus user interface after performing the optimization for each city. Each square represents an iteration, where the pareto front iterations are highlighted with circles. The graph includes all the simulated configurations with their thermal EUI, and genetic diversity values that appears when you hover over a square. In order to take a photo of the chosen configuration, each case was generated through clicking on its square and selecting the command reinstate solution. This option allows for the regeneration of the building form model in the rhinoceros while presenting its objective functions, and dynamic parameters values in grasshopper. Figure 2 shows that the lowest thermal EUI value reached for Cairo case was 92.62 kWh/m² per year. While figure 3 shows the lowest thermal EUI reached for London is 25.49 kWh/m² per year. And figure 4 shows the lowest thermal EUI reached for Chicago is 61.29 kWh/m² per year. Better values for thermal EUI could be achieved through increasing the number of generations (optimization time) to include more numbers of tested design configurations. In this study, the optimization time taken to perform the five generation was around 5 hours using a laptop with a 7th Generation Intel® Core™ i7-7700HQ Processor (2.80GHz, up to 3.80GHz with Turbo Boost, 6MB Cache), and 16.0 GB installed memory (RAM). Optimization process time could be decreased through the usage of better computer resources.

Figure 2: Cairo Simulation results presented in graph between genetic diversity and thermal EUI.

Figure 3: London Simulation results presented in graph between genetic diversity and thermal EUI

Figure 4: Chicago Simulation results presented in graph between genetic diversity and thermal EUI

Cairo pareto front results were selected from the results graph in Octopus to represent a random selection of variety of generated forms with different thermal EUI values that starts from the optimal solution till it reaches the worst solution. The pareto front configurations are presented in figure 5 with the percentage decrease or increase in thermal EUI in reference to the initial squared form. The configurations are ordered according to their thermal EUI performance from the optimal to the worst configuration with the base case located in between with 0% value. Figure 5 shows that optimal solution tended to expand the building dimension along north-south axis. And to expand the top and bottom floors along east-west axis which causes the shading of the middle floor west and east facades. In addition to rotating the building slightly towards north-west direction. While the worst configuration tended to increase the height of the building floors and to avoid the expansion of the whole building along north-south axis, in addition to tilting the building to completely face the north-west direction.

Generally, it appears that shading the ground and/ or the middle floor enhances the thermal EUI of the initial box in Cairo case. However, there still exist top enhanced solution in the pareto front that has no self-shading as seen in the seventh configuration that was enhanced by 17.98 % in reference to the base case. It is also obvious that irregular forms with square shaped foot print is the best in terms of thermal energy performance. However, irregular forms with rectangular shaped foot print can also provide enhanced thermal

energy performance when compared to the initial regular form as seen in the fifth, sixth, and eighth configurations.

Figure 5: Cairo Pareto front solutions and the base case. Design configurations are ordered from the optimal to the worst solution (from left to right, and from top to bottom). (a: percentage of increase or reduction in thermal EUI in comparison to the base case). All perspectives are taking from the same north-west view angle and position, and each perspective is preceded by a plan. North arrow is presented in the left side of plan and bottom right part of perspective.

While in Cairo there are thirteen enhanced solutions before the base case in the pareto front, London and Chicago (figures 6, and 5) have only nine better enhanced solutions before the base case. In both London and Chicago, the optimal forms tended to expand the whole building and the three floors to the maximum to take the shape of a larger regular square shaped form, while keeping the building height fixed at 3 meters. While the optimal configuration for London tilted the building slightly towards north-west direction, optimal configuration for Chicago kept the orientation same as the base case.

In London, and Chicago, the worst cases resemble Cairo worst configuration in increasing the height of the building floors and in avoiding the expansion of the whole building along north-south axis. But the three worst cases differ in the expansion of floors and the degree of rotating the building towards north-west direction. However, building rotation in the three cases existed in both enhanced forms and the forms with lower energy performance. In

both London, and Chicago slight shading appeared in two and one enhanced configurations, but extreme self-shading appeared in 6 worse cases in London and in one of the cases with least performance in Chicago.

Figure 6: London Pareto front solutions and the base case. Design configurations are ordered from the optimal to the worst solution (from left to right, and from top to bottom). (a: percentage of increase or reduction in thermal EUI in comparison to the base case). All perspectives are taking from the same north-west view angle and position, and each perspective is preceded by a plan. North arrow is presented in the left side of plan and bottom right part of perspective. Scatterplots

Scatterplots presented in this section shows the relationship between each dynamic parameter against annual thermal EUI objective function in each of the three cases. They are developed using the simulation results of around 500 iterations for each of the three cities. Scatterplots of each dynamic parameter against thermal EUI for the three cities are presented in one column to ease the comparison between different local climate conditions. Each circle in a scatterplot represents an iteration and the dotted line represents the trend direction. Annual thermal EUI values are presented in the y-axis in kWh/m², while each of dynamic parameter's values are presented in the x-axis with their unit.

In [7], the author stated that noticeable trend in a scatterplot reflects a strong impact of the dynamic variable. In this research, the scatterplots of expansion of the whole building along one axis against thermal EUI presented in figure 8. And the scatterplots of the

expansion of each floor along the other perpendicular axis against thermal EUI presented in figure 9 show the most obvious decreasing trend. This means the manipulation of both form dynamic parameters have a positive impact as decreasing trend reflects decrease in thermal EUI.

Figure 7: Chicago Pareto front solutions and the base case. Design configurations are ordered from the optimal to the worst solution (from left to right, and from top to bottom). (a: percentage of increase or reduction in thermal EUI in comparison to the base case). All perspectives are taking from the same north-west view angle and position, and each perspective is preceded by a plan. North arrow is presented in the left side of plan and bottom right part of perspective.

On the other side, scatterplots of the increase in the floor height against thermal EUI show the most obvious increasing trend. This shows it has a negative impact as it causes the increase in thermal EUI. Finally, building orientation has increasing and decreasing trend in each of the three cities, which shows that building orientations values needs to be adjusted to keep values that cause a positive impact only. For example, in London case in figure 10 the lowest thermal EUI value is reached in the area between values 0, and 0.5 radians. Therefore values larger than 0.5 can be eliminated easily from the building orientation values dynamic parameter to avoid the resting of more useless values which causes the increase in calculation time.

Figure 8: Scatterplots of average expansion of the three floors along one axis against thermal EUI for the three climates.

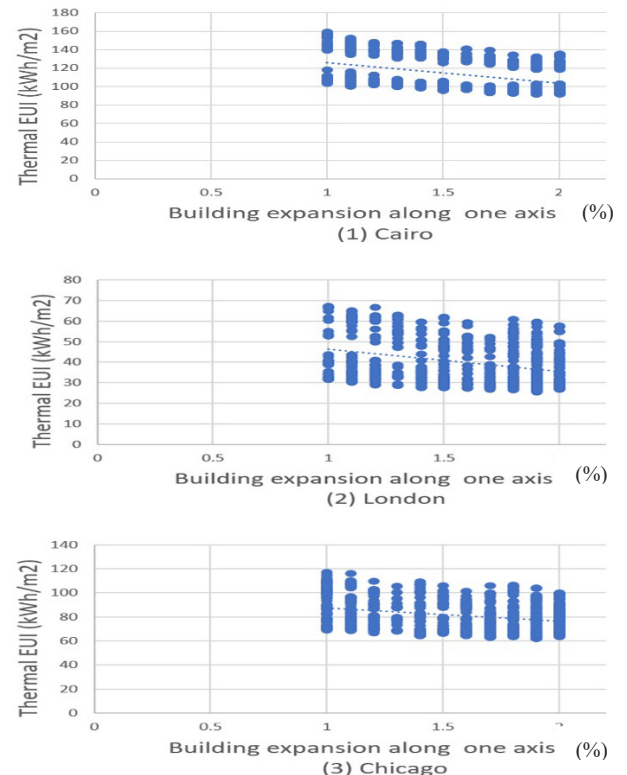

Figure 9: Scatterplots of Building expansion along one axis against thermal EUI for the three climates

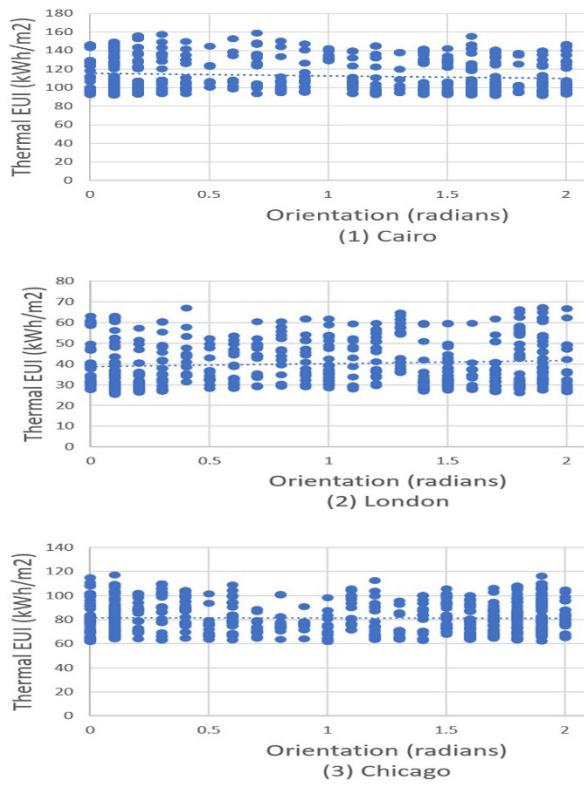

Figure 10: Scatterplots of building orientation against thermal EUI for the three climates

Figure 11: Scatterplots of floor height against thermal EUI for the three climates

Generally, it appears that each dynamic parameter has the same positive or negative impact on the thermal EUI objective. However, there are still differences between the three cities. For example, scatterplots of both average expansion of the three floors, and Building expansion against thermal EUI show an obvious decreasing trend. But, in both types, Cairo plots has the highest obvious decreasing trend. On the other side, scatterplots of increasing in floor heights against thermal EUI show the highest obvious increasing trend, but Cairo case also has the highest obvious increasing trend.

4. Conclusion

The objective of this research is to propose EPBFM method for optimizing open office building form and orientation for thermal energy performance at the early stage of the design process. This proposed method allows for the generation of numerous design configurations from the initial problem set. After optimization all generated forms are ordered from the highest to the lowest in terms of thermal energy performance in the pareto graph. This workflow allows for the generation of different optimal forms that differs in accord with the difference in local climate conditions. The study uses the same initial problem set and same form and orientation dynamic parameters. The evaluation objective function used minimizes thermal load (cooling and heating loads) while promoting diversity. The percentages of reduction or increasing of thermal load of new generated forms in reference to the base case differed also in accord with the difference in climate zones. In this research the thermal energy use intensity (EUI) was decreased by 22.76% in the arid climate, 29.7% in the temperate, and 19.2 in the cold climate, in comparison to the initial square shaped building form. Scatterplots were developed to test the role of each dynamic parameter in enhancing or worsening thermal energy performance. The expansion of the building along one axis, and the expansion of floors along the other perpendicular axis proved to have the highest obvious positive impact on enhancing thermal EUI. While manipulation of building height has the highest obvious negative impact.

Future application to other climate zones is recommended to expand the current work. The current research considers the form and orientation dynamic parameters only to understand their effect on enhancing thermal energy performance and how the optimal architectural form and its orientation differs according to local climate conditions. The consideration and manipulation of envelope parameters such as, window-to-wall-ratio, and shading devices is also recommended to further enhance the thermal energy performance. Other objective functions also can be added to expand the work such as, cost, and acoustics. It is important also to note that in this research optimization process were stopped after performing six generations for each of the three cases. The number of generated alternative design configurations increases with the increase in the generations, thereby increasing the number of generations is recommended to explore more design alternatives. This can be achieved through the usage of better computer resources or increasing the calculation time.

Conflict of Interest

The authors declare no conflict of interest.

Gum Arabic

Setting Time

Workability

Compressive Strength

ABSTRACT

The present work focuses on the effect of adding gum Arabic on the setting time of cement pastes, workability, and compressive strength of concrete. For workability and compressive strength liquid gum Arabic was added to concrete mixes at ratios of 0.0% (control mix), 0.3%, 0.5%, 0.7% of the weight of cement. In addition, from 0.1% to 0.7%, ratios of GA were added to cement paste to investigate the effect of this admixture on the initial and final setting time of cement. Concrete cube specimens cast using metallic molds measuring 150 x 150 x 150 mm, and cured at 7, 28 and 91 days. From the results obtained it has been shown that the setting time of cement paste delays with increasing GA ratios. The amount of slump of fresh concrete increases largely with increasing GA ratios. GA develops considerably more compressive strength than normal concrete. The highest strength was observed at 7% of GA at all ages.

1. Introduction

Some chemical admixtures are very expensive and liable to damage while bad storage. So, the major problem in the use of chemical admixtures is the high prices, leading to increased project costs and are therefore fewer corporate profits as a result. Researchers began to think to solve this problem through experiments on local materials and cheap price and study the possibility of use as a cheap admixture such as Gum Arabic. Gum Arabic may have water-reducing properties and a dispersing effect and has been used as pumping aids [1]. Welan gum, which is in the same class as Gum Arabic, has been reported to increase cohesiveness [2].

Gum Arabic is soluble in water, edible, and used primarily in the food industry and soft-drink industry as a stabilizer. The gum contains an oxidizing enzyme that may affect the preparation containing formulations that are easy to oxidize. The moisture content facilitates the dissolution of both carbohydrates combined with water and protein not bound with water in Gum Arabic solution [3]. According to Standard Association of Australia (SAA), pumping aids admixtures can be classified through natural gums, which are soluble in water [4].

2. Literature Review

Previous studies have shown the effects of different types of gum Arabic in concrete mixes; such as: [5], presented a paper on Arabic gum biopolymer (AGB) focusing on the impact of added AGB on the setting time, durability of concrete, and workability. They further performed X-ray fluorescence tests on cement-AGB mix powder for determining its chemical structure for estimating carbonation depth in AGB concrete samples for

evaluating durability. The findings of this study indicated that initial setting time and fluidity of the AGB mortar elevate progressively with AGB content to a maximum weight fraction of 0.9% AGB. On the contrary, the increase in AGB dosage proportions was because of the slight reduction in density.

The Effects of Gum Arabic (GA) Admixture on the Mechanical Strengths of Cement Paste and Concrete using various ratios of GA as percentages of cement weight was investigated [6]. Content was taken as 420 kg/m³ with ratio of 0.5, to produce cement pastes and concrete specimens that were cured for 90 days in water. The research concluded that GA delayed the setting time of concrete and increased the compressive and flexural strength of concrete.

The impact of Gum from Acacia Karroo (GAK) as a retarding admixture in cement pastes was investigated [7]. The researchers compared compressive strength of cement mortars with 0.7, 0.8, and 0.9% weight of cement and w/c ratio of 0.5 were compared to those with (w/c) ratio of 0.44 but dosage of GAK. They also prepared concrete samples using higher dosages of GAK (1, 2 and 3% wt of cement) and a water binder (w/b) of 0.61 and compared to those having the dosage but w/b ratio was reduced.

Similarly, in [8], the author studied the effect of GAK as a Water-Reducing Admixture in Concrete. Different ratios of GAK were employed for studying a slump test, density, and compressive strength. The findings of this study indicated that slump elevated by 200% at a 2% dosage of GAK, which facilitate reduction of water-to-binder ratio from 0.61 to 0.48 with a 3% dosage for samples. Reduction in w/b resulted in increased compressive strength of 37.03% above the control after 180 days of curing for a 3% dosage. The study concluded

*Corresponding Author: Ali Eltom Hassaballa, tomali99@yahoo.com

www.astesj.com

<https://dx.doi.org/10.25046/aj060229>

that Gum from GAK is utilized in concrete as a water-reducing admixture in order to produce greener and sustainable concrete.

There was a study on effect of Gum extraction from trees on mechanical properties of concrete was conducted [9]. The study presented the concrete strength determination with gum as a natural admixture using dosages of 0.5%-1%, wt% by cement. Gum Arabic, Badam gum, Tragacanth gum and Neem gum were used. Cube specimens of size 100mm*100mm*100mm size were casted and water cured for 7, 28 and 56 days. It was found that maximum compressive strength was achieved when using 0.5 % of Badam gum.

A study of using liquid gum instead of solution of sodium silicate as adhesive material to improve cold bonding strength was prepared. This study resulted in cold bonding strength more than 1.38MPa. in [11], the author investigated the impact of partial removal of cement with Neem Gum for determining the strength attributes of high-performance concrete and added to concrete mixes at various ratios (0.1%, 0.2%, 0.4%, 0.6%, 0.8%, 1.0%, 1.2% & 1.5%) by weight of cement content. The paper concluded that when using Neem gum in the form of powder, the compressive strength was slightly reduced with an elevation in the ratio of Neem gum in concrete mixes at ages 7, 21 and 28. On the contrary, high compressive strength concrete with better workability was shown through modified gum in its liquid state.

A research to evaluate balling in sisal reinforced concrete using gum Arabic, known for increasing the workability of plain concrete was presented [12]. Performance of two categories of 100 mm concrete cube specimens were considered, comprising control mix of 1:2:4 sisal fiber-reinforced concrete with 3% volume fraction (Vf) of the fiber cut into 30 mm length and gum Arabic of 0.2%, 0.4%, 0.6%, and 0.8% the weight of cement. Water/cement ratio was fixed at 0.6. The concrete cube specimens were cured at 7, 14 and 28 days. It is found that the addition of 0.8% gum Arabic by weight of cement to sisal reinforced concrete decreases balling, improves the workability of concrete mix and increases the strength of the concrete. Use of gum Arabic (acacia seyal) as concrete admixture was conducted [13]. This study aims at finding alternative indigenous Sudanese material for a concrete admixtures that are necessary for casting concrete in hot weather of the Sudan. The European standards BS EN 934 & BS EN 480 have been used as a paradigm to classify TG functionality as concrete admixture. water/cement ratio(W/C) of 0.58 and consistence (slump=70±10) mm were adopted. The 0.8%TG by cement weight has been found to be the most appropriate dosage with water reduction levels of 11.5% and 7.5%. Also, TG satisfied all criteria set by BS EN 934-2:2009 for a set accelerating water reducer (SA\WR). In [14], the author presented a conference paper on the suitability of Gum Arabic in terms of its competence for acting as a plasticizer in concrete for producing self-compacting concrete.

3. Aims and Objectives

This paper aims to investigate the effects of gum Arabic on the setting time of ordinary Portland cement and the properties of fresh and hardened concrete. GA is used herein as an alternative indigenous material for concrete admixtures that are necessary for casting concrete in hot weather of Kingdom of Saudi Arabia (KSA).

There is a dire need for using admixtures, specifically in Saudi Arabia, that have certain modified characteristics of concrete with respect to being well-suited with Saudi climatic

conditions. For instance, there is an instant loss of workability because of high evaporation of mixing water, and the tendency adds more water to the mixture when concrete is mixed at increased temperatures. It should be noted that chemical admixtures can be utilized for elevating workability regardless of elevating the extent of mixing water. Therefore, there is a prerequisite for developing natural, environmentally friendly, and inexpensive admixtures. This study tests the effect of Gum Arabic on the mechanical characteristics of concrete. A slump test, air entrainment, and compressive strength were conducted for determining concrete performance at different dosages and water-to-binder ratios.

4. Materials and Testing Procedure

The raw materials used in this research include cement, fine aggregate, coarse aggregate, water and gum Arabic (GA). Ordinary Portland Cement, meeting the specification of ASTM C 1437 [15], was used in this work.

The raw gum was processed into mechanically ground form; where 50 kg of the grinded gum was processed in the fluid bed drier machine for acquiring granulated form. The process of granulation was followed by a protocol to perform the procedure of granulation. The machine was programmed to have a temperature range of 400°C outlets and 7°C inlet while spraying of 300 mL of water per minute. The process was recurrent in a frequency of five times every 10 min.

Natural fine aggregate and crushed stone coarse aggregate meeting the requirements of ASTM C 33 [16] were used. The maximum size of coarse aggregate was 20 mm. The slump test was carried out immediately after mixing concrete for all samples. The compressive strength test of concrete cubes was carried out for 7, 28 and 91 days of age. Liquid gum Arabic was added at ratios of 0.0% (control mix), 0.3%, 0.5% and 0.7% by the weight of cement. This was conducted for finding the effect of Gum Arabic on the characteristics of slump test and compressive strength concrete. Concrete cubes were cast using metallic molds measuring 150 x 150 x 150 mm.

Figure 1: Unprocessed Gum Arabic

Figure 2: Processed Gum Arabic

All concrete specimens were prepared through ordinary Portland cement (grade 52.5 MPa) mixed with 25% unclassified fly ash. Pretoria Portland cement donated all of the cement and fly ash. The composition of cement and fly ash was determined through X-ray fluorescence.

5. Concrete Mix Design

Concrete mix design for this work was prepaid according to American Concrete Institute (ACI-211.1) [17]. The constituents of this mix, the ratios and quantities of GA are shown in Table (1).

Table 1: Concrete mix design constituents

Constituents	Weight (kg/m ³)		
Cement	7.785		
Water	3.42		
Fine aggregate	8.46		
Coarse aggregate	15.75		
GA (%): (0.3, 0.5 & 0.7)	0.023	0.039	0.054
Total	35.44	35.45	35.47

6. Results and Discussion

6.1. Consistency and setting time of cement paste

Table (2) shows the results of the physical properties of ordinary Portland cement used in this paper, without adding GA (control sample) [15]. This table shows that the control sample is in conformity with the standard.

Table (3) shows the results of the initial and final setting time of cement paste by adding different ratios of GA. Results show that the measured initial setting time depends on the dosage of GA percentage as presented in Figure (3). There is a slight increase in initial setting time at the ratios of GA ranging from 0.0 % to 0.3% and then large increases starting from 0.4% to 0.7% of GA as shown clearly in Figure (4). The final setting time also changes in the same manner as in initial setting time. It increases with increasing of GA dosages as shown in Table (3) and Figure (4). For the delay in initial setting time GA can be used as an admixture in hot weather and as reducing water admixture in concrete mixes.

On the contrary, it should be noted that this is a type of false setting that has been excluded by re-mixing. It might be because of the hydrophilic nature of GA that adsorbs water with high affinity, but issue it at the time of re-mixing. Similarly, it did not influence the final setting time as retarded it by 7 minutes.

Table 2: Results of physical tests of cement paste (control mix)

No	Test	Results	ASTM C150
1	Standard consistency of cement paste (water %)	25%	25% -33%
2	Standard of cement paste reading (Vicat apparatus) (mm)	34	33 - 35
3	Initial setting time (min)	95	Not less than 45 min
4	Final setting time (min)	149	Not more than 375 min
5	Fineness %	2%	Not more than 10%

Table 3: Initial and final setting time of cement pastes using different ratios of GA

No	GA (%)	Initial setting time		Final setting time	
		(min)	(hr)	(min)	(hr)
1	0.0	95	1.58	137	2.28
2	0.1	120	2	149	2.48
3	0.2	124	2.07	153	2.55
4	0.3	136	2.27	160	2.67
5	0.4	174	2.9	184	3.07
6	0.5	321	5.35	367	6.12
7	0.7	483	8.05	514	8.57

Figure 3: Initial setting time of cement pastes using different ratios of GA

Figure 4: Final setting time of cement pastes using different ratios of GA

Figure 5: Initial and final setting time of cement pastes using different ratios of GA

6.2. Sieve analysis for fine and coarse aggregate

Grading coarse and fine aggregate was determined by a sieve analysis (ASTM C33) [16]. From sieve analysis the fineness modulus (FM) of sand was found to be 2.2, which fell within 2.2 –2.6, which is categorized as fine sand fineness [17]. (FM=2.2) was used in estimating proportions coarse and fine aggregate in concrete mixture. Grading results for fine and coarse aggregates are shown in Figures (6 and 7).

Figure 6: Sieve analysis for coarse aggregate

Figure 7: Sieve analysis for fine aggregate

6.3. Results of slump tests

The result of slump tests is shown in Table (2) and graphically in Figure (5). Generally, it has been shown that slump increases with increasing GA ratios. At a 0.3% dosage, there was a considerable increase in the slump of 28.5% compared to the control. At 0.5% gum Arabic, the slump increased to 107 mm, while at 0.7% gum Arabic, slump recorded was 210 mm, thus indicating increase of 205.7% and 500% respectively when compared to the slump of the control mix.

It is worth noting that the dosage of 0.7% of GA mix showed considerable level of bleeding. Also, it was observed that for concrete mixes containing 0.7% of GA dosage the cubes demolding required two days.

Table 4: Results of slump tests using different ratios of GA

GA (%)	Slump results (mm)
0.0	35
0.3	45
0.5	107
0.7	210

Figure 8: Slumps (mm) using different ratios of GA

6.4. Results of compressive strength

Table (5) shows the average compressive strength of the concrete cubes taken at ages of 7, 28 and 91 days. There were large increases in strength when the dosages of GA and curing of samples were increased. The maximum strength was recorded at 0.7% of GA for all ages.

At low level dosages of 0.3% – 0.5% and for age of 7 days, there was a decrease in compressive strength compared to control mix. This was probably due to the fact that low dosages of GA with early ages of concrete GA have no significant effect on the properties of hardened concrete.

At a 0.7% dosage, strength increased significantly in all ages, probably due to the fact that this was the optimum dosage. At 0.7% of GA the differences in strength reached up to 2.6 %, 16.0% and 20%, for ages of 7, 28 and 91 days, respectively compared to control mix as shown in Figure (6).

The compressive strength of samples was enhanced through prolonged curing up to 91 days. On the contrary, the value of the control was not reached by this strength. At this age for samples, compressive strength varies between 7.3% - 11.5%. A compressive strength below the design mix of 34 MPa was yielded for samples treated with GAK at a w/b ratio of 0.61.

Nonetheless, the change in values between samples with different dosages was fewer than 5%. This might be because of the less effect of Gum Arabic at later age. This is a possible explanation because of the mitigation in the rate of cement hydration caused by the inclusion of Gum Arabic, reducing the dissolution of alkalis in the pore fluid [18]. Previous studies have indicated a reduction in compressive strength while using polysaccharide gums [19, 20].

Table 5: Results of Concrete compressive strength tests for ages of 7, 28 and 91 days using different ratios of GA

GA (%)	Average Compressive Strength (MPa)		
	7 days	28 days	91 days
0.0	34.13	41.746	50.10
0.3	30.09	43.065	52.00
0.5	33.28	46.997	57.00
0.7	35.02	48.499	60.20

Figure 9: Concrete compressive strength tests for ages of 7, 28 and 91 days using different ratios of GA

7. Conclusion

In this paper, liquid gum Arabic was added to concrete mixes at ratios of 0.3%, 0.5%, 0.7% of the weight of cement in order to

find out its effect on the properties of fresh and hardened concrete. From the results obtained it may be concluded that:

1. The setting time of cement paste delays with increasing GA ratios which will make it an ideal plasticizer for concrete in situations where delayed setting time is required.
2. The amount of slump of fresh concrete increases largely with increasing GA ratios.
3. It was found that GA develops considerably more compressive strength than normal concrete. the highest strength was observed at 7% of GA at all ages.
4. GA can be used in concrete as an admixture in hot weather and as a water reducing admixture in concrete mixes which is environmentally-friendly, thus producing sustainable and greener concrete.
5. GA can be used as an admixture on the flexural and tensile strength as well as permeability of concrete for enhancing the performance of concrete in the construction sector.

ABSTRACT

Distribution is the main activity in integrated product supply chain management. In the pharmaceutical industry, the process of drug distribution is important because of the handling, storage, and distribution of medicinal products with good standards and quality. The problem that occurs in the pharmaceutical industry is the circulation of counterfeit drugs by related parties, for example, unofficial or unregistered distributors or data collection for unregistered medicines circulated by distributors. Permits misused from drug manufacturing processes until they are distributed or circulated do not comply with the Food and Drug Supervisory Agency standard provisions. These problems must be resolved quickly with technological support to facilitate the distribution process in recording data distribution, providing data security, and traceability of transactions between related parties. This study proposes a good drug distribution model by applying blockchain technology. The Model development uses a qualitative approach and a user center design. The result of this study is a validated drug distribution model with blockchain technology. The model has the characteristics of transparency, security, traceability, decentralization, automation, immutability, and reliability. This model can help the government ensure public health and safety by ensuring that the drugs received are of good quality, thereby increasing the community safety and health and trust in drugs in circulation.

1. Introduction

Supply chain management is a process that links suppliers to consumers [1]. The most important distribution process is the distribution process, namely contacting producers to consumers [1, 2]. Distribution encourages company profitability because of the impact of logistics costs incurred [3]. Distribution is the main activity in the integrated supply chain management of products. In the pharmaceutical industry, the process of drug distribution is important because of the handling, storage, and distribution of these products [1, 3]. The distribution process has an entity involved and responsible for the distribution process to run properly. The distribution process in Indonesia already has a drug distribution process guideline in the regulations of the BPOM. Badan Pengawas Obat dan Makanan (BPOM) or English name Drug and Food Supervisor. Good drug distribution guidelines aim to ensure drug quality and identity during the distribution process [4]. Good distribution fulfills the responsibilities of entities

involved in various aspects of the supply chain distribution process. Indonesia has made the pharmaceutical industry focus on the 2015-2035 national industrial development master plan (RIPIN) to improve peoples quality of life [5, 6]. The government also guarantees the availability of pharmaceuticals and medical devices according to Presidential Instruction number 6 of 2016 as an effort to improve health services in the context of national health insurance [7]. The vision and mission of national industrial development, various problems occur with the rampant distribution of counterfeit drugs by related parties, such as unofficial or unregistered distributors or unregistered records of drugs distributed by distributors properly and misuse of a permit from the process of making drugs to be distributed according to the standard provisions of the BPOM [8, 9]. Apart from this, there is poor governance in the data collection of drugs and distributors registered at BPOM [10]. This is also reproduced in violations that occur in the sale of counterfeit and expired drugs, other types of drugs that should not be done in pharmacies [11]. The problem must be resolved quickly by identifying the parties involved in the

*Corresponding Author: Meyliana, Email: Meyliana@binus.edu

drug distribution process in an integrated network so that it is easy to trace. Technology support is important to simplify the distribution process in recording data, providing data security, and traceability of transactions between related parties. This research proposes blockchain technology to be applied in the distribution process that occurs. Blockchain technology has the characteristics of transparency, security, traceability, decentralization, automation, immutability, reliability in carrying out the distribution process in the pharmaceutical industry [12]. This blockchain technology has been implemented in many industries [13]. Blockchain technology provides certainty in the validation of the distribution processes recorded and is well integrated with each other. This makes the tracking process easier to do to reduce theft, forgery, and increase data security [14, 15].

The last few years of research that has occurred have only provided a foundation for developing theories on information resource management in distributed virtual organizations. This study also does not fully regulate the supply chain process of the pharmaceutical industry but only evaluates the framework for the development and production processes [16, 17].

This research will focus on building a drug distribution model in the pharmaceutical industry using blockchain technology. The model built can improve the pharmaceutical industry distribution system, which is more integrated with one another so that it can be trusted, accountable, transparent, and protected from the circulation of counterfeit drugs [18]. The model can help the government ensure the community health and safety by ensuring the drugs received are of good quality, thereby increasing public trust.

2. Theory

2.1. Supply chain Management

Supply chain management is the management process of the materials used to create products, the production process, and the final products final delivery [19]. The management is made a chain that is tied to each other, and it can be said that the supply chain. Supply chain management that is carried out as a whole will be an added value that is effective and economical in running a business. The positive impact that occurs is the company is able to know and ensure a product made from good materials from suppliers, the production process to ensure that the product is made to arrive properly and with quality in the hands of consumers [20]. Supply chain management integrates various key processes in the company so that it aligns all activities from suppliers to customers to provide cost reduction and flexibility in activities [21].

2.2. Value Chain

The porter value chain is a value chain in which each activity will influence the each other to provide the companies competitive power or organization. Porter defines several five main activities, namely: incoming logistics, operations, outgoing logistics, marketing and sales, and services and support activities: procurement, technology development (including Research & Development), human resource management, and infrastructure (planning systems, finance, quality, management information, etc.) [22, 23]. The basic model of the Porter Value Chain Model is as follows:

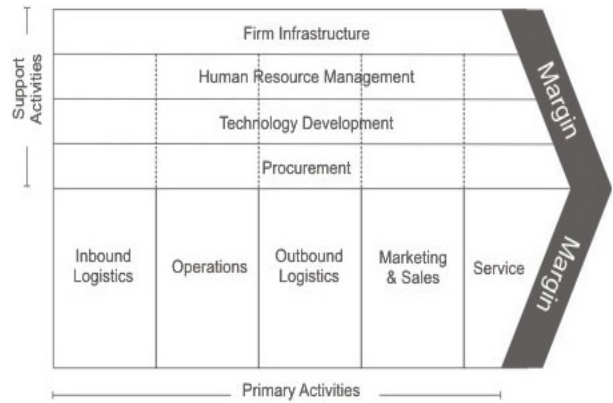

Figure 1: Value chain Porters [23]

2.3. Blockchain

Blockchain consists of the words block and chain, which can be interpreted as blocks that are tied in chains to one another. Satoshi Nakamoto first introduced blockchain in cryptocurrency [24, 25]. Blockchain implements decentralized or distributed data storage. Blockchain has the characteristics of being immutable and append-only (can only be added). It is a distributed ledger, and all data is copied to network participants (nodes) [26, 27]. As time goes on, blockchain can be used in enterprise systems by providing a new touch in smart contracts [28]. Smart contracts are logic that is sequentially created by business processes to transact in the blockchain system based on an agreement between two people [26, 27].

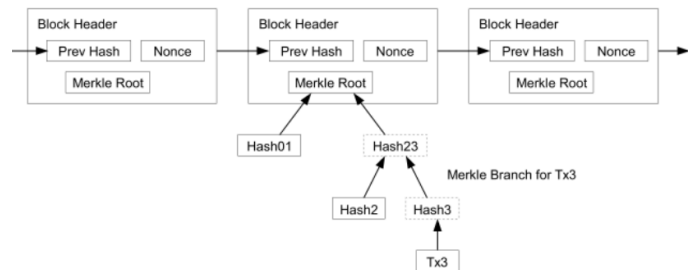

Figure 2. Blockchain [25]

2.4. Good Distribution Practice

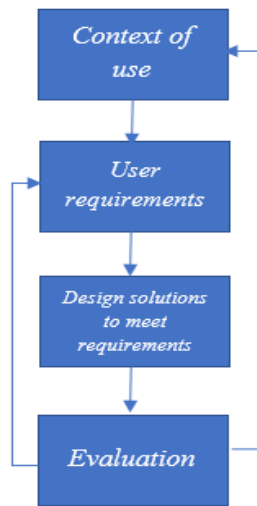

Good distribution practice (GDP) or in Indonesian country called "Cara distribusi obat yang baik" (CDOB). Good drug distribution methods are used to ensure that drugs are consistently produced and controlled to achieve quality standards in accordance with the intended use and required in the distribution permit and product specifications.

2.5. User-Centered Design (UCD)

User-Centered Design (UCD) is a framework in doing design by looking at the users point of view, and it should be the users point of view [28,29]. This UCD has the following steps:

1. Context of use is done to get what the user wants.
2. User requirements are made to adjust the design to the wishes of the user
3. Design solutions to meet requirements are carried out to find solutions in making a design based on the needs of the user.

4. Evaluation is the evaluation of the design from user feedback so that the design is appropriate.

3. Methodology

This research methodology with a qualitative approach and user center design techniques. The constructed model is based on literature studies and focus group discussions (FGD) with the pharmaceutical industry. This FGD with 4 domain experts from the division related to the drug distribution process, including the logistics department, the finished drug warehouse, marketing and sales, Quality Control, and Quality Assurance. Discussions were carried out with experts with several opportunities to ensure that the models design was in accordance with the pharmaceutical industry needs. In this discussion process, the experts said they agreed with the model being developed. With this validated model, it is possible to be applied in the pharmaceutical industry.

3.1. Context of Use

This stage searches for problems in users related to the distribution process to the pharmaceutical industry, pharmaceutical wholesalers, and pharmacies. The problem finding was carried out with a forum discussion group on the pharmaceutical industry. This discussion forum was attended by marketing sales managers, the production planning and inventory control section, the finished drug warehouse. The problem that occurs is that many drug distribution processes that occur are not in accordance with government regulations. For example, there are still many pharmaceutical wholesalers that are not properly registered, drug distribution data are not well recorded, and each actor does not have integration. So, it requires technology that can handle problems. The author offers blockchain technology that is used to enable each related party to integrate data and information properly and record irreversible drug distribution data.

3.2. User Requirements

This stage will adjust the design to the wishes of the user by conducting interviews with a forum discussion group in related parties. From the interview results, each party has confirmed to agree to the model being developed. The model developed describes the distribution process well with blockchain technology.

3.3. Design solutions to meet requirements.

This stage re-validates the parties involved in the drug distribution process to get the distribution model built that meets the requirements.

3.4. Evaluation

Evaluate the design from user feedback so that the design is in accordance with conducting back interviews with a forum discussion group in related parties. In addition, this evaluation can also get a view of the model being developed.

4. Analysis and Discussion

The development of a good drug distribution model is carried out with a user-center design approach, which is carried out in several stages. This study discussion relates to the model developed with the literature and based on the guidelines for good drug distribution established by the Republic of Indonesia Food and Drug Administration. This model starts from the value chain (outbound logistics, distribution, marketing and sales, and service), related stakeholders (warehouses, distributors, hospitals/clinics/pharmacies, drug stores, and end consumers/patients).

The blockchain technology that tells the data will be stored in the blockchain during the distribution process. Blockchain implementation in this distribution process begins in the pharmaceutical industry getting drug purchases from drug distributors and sending drugs back to distributors, and the data will be stored on the blockchain database, then the drug purchase process is also carried out by pharmacies, drug stores, and hospitals to distributors. The data will be stored in the blockchain. Consumers make drug purchases from pharmacies, drugstores, and hospitals. The data will be recorded in the blockchain database.

The last is the GDP Aspect in the industry, consisting of 9 aspects (quality management, management, personnel organizations, buildings and equipment, operations, self-inspection, complaints of drugs or presumed counterfeit drugs and process recall, transportation, distribution facilities based on contracts, documentation). The model developed can be seen in Figure 4.

The main business processes in the pharmaceutical industry are divided into 2 major areas, namely good manufacture practice (GMP) in Indonesia called "cara pembuatan obat yang baik" (CPOB) and Good distribution practice (GDP) in Indonesia called "cara distribusi obat yang baik" (CDOB). CPOB starts from the industry doing development and research on drugs that want to be produced. After that, purchase raw materials from suppliers and then make production. Production results will be stored in the finished drug warehouse. Meanwhile, CDOB starts from finished drugs ready for distribution to customers, from the pharmaceutical industry to pharmaceutical wholesalers, pharmaceutical wholesalers to health services (pharmacies, drug stores, hospitals). Further health services can distribute to the public. The complete picture of the CPOB and CDOB models can be seen in Figure 5.

5. Discussion

5.1. Value chain

This value chain starts from an industrial warehouse, a storage place for drugs produced and ready to be produced. Detail process distribution:

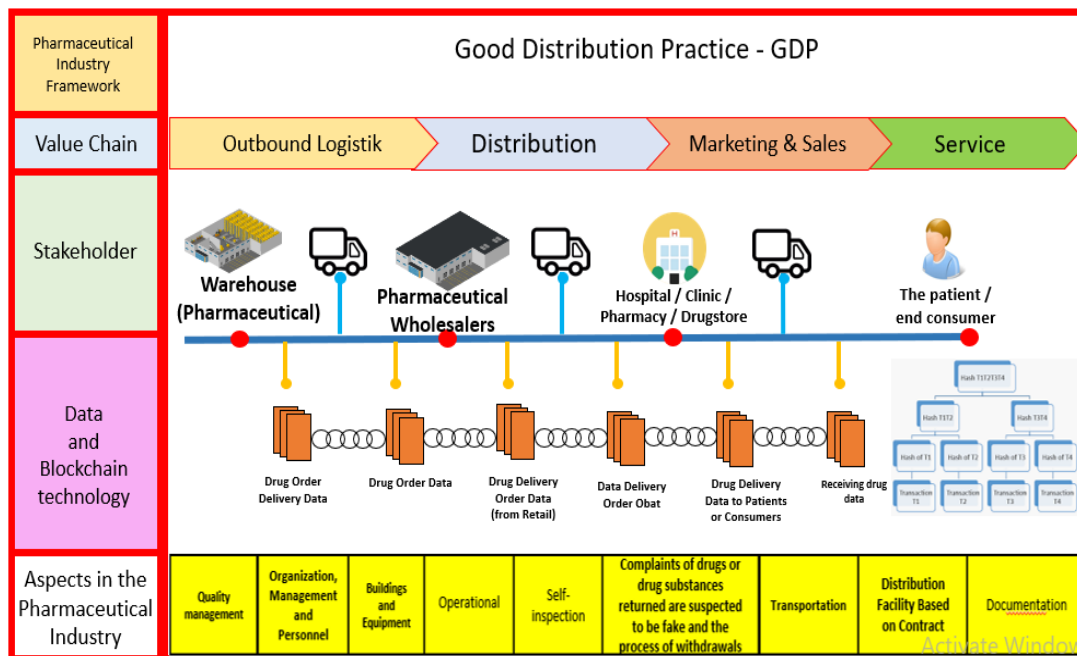

Figure 4: Good distribution Practice Model with Technology Blockchain

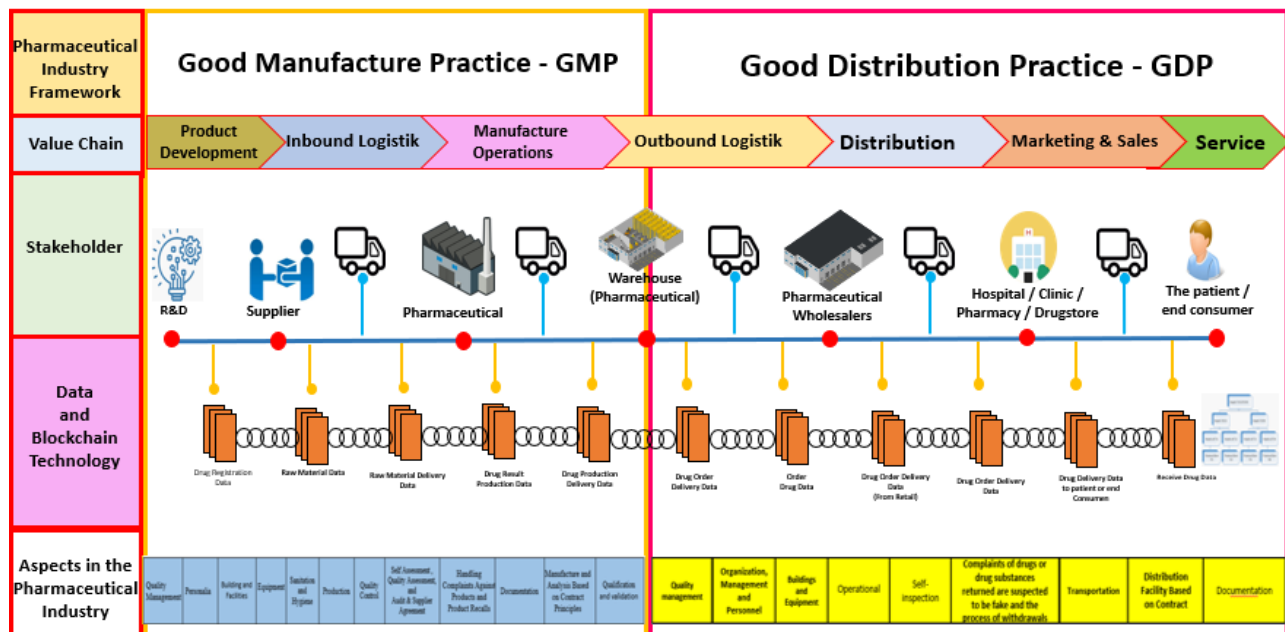

Figure 5: Good Manufacture Practice (GMP) and Good Distribution Practice Model with Technology Blockchain

Outbound logistics

Outbound logistics are activities that involve the distribution of finished products to customers. For example, sending an existing car via a service to car dealers is an outbound logistics activity. Inbound Logistics refers to the transportation, storage, and delivery of goods that enter the business. Outbound Logistics refers to the same for goods going out of business. Inbound and outbound logistics combine in supply chain management, as managers seek to maximize distribution network reliability and efficiency while minimizing transportation and storage costs. Understanding the differences and relationships between inbound and outbound logistics can help develop a comprehensive supply chain management strategy.

2. The distribution process for distributors to retailers (Hospital / Clinic / Pharmacy / Drugstore) accepts drug orders whose data is recorded on the blockchain system. Then the distributor sends the drug according to the retailer order, and then the data is recorded into the blockchain system.
3. The distribution process occurs at the retailer (Hospital / Clinic / Pharmacy / Drugstore) with the end customer, and the data will be recorded into the blockchain system.

Distribution

Distribution is a marketing activity carried out by distributors or intermediaries to deliver goods or services from producers to consumers. Delivery of goods can also be from the manufacturer, industry, or manufacturer to retailers or retailers.

Marketing and sales

Marketing acts as a think tank that designs product development and marketing strategies. Sales are a team implementing the promotional strategy to increase product sales.

Service

Service is done to keep Consumers can have the interest to Return to buy into a sale. Thus it is necessary to provide services to Consumers well and in accordance with the demands of Consumers.

5.2. Stakeholder

Stakeholders are parties involved in the distribution process in the pharmaceutical industry where there is a pharmaceutical industry (drug maker and provider), pharmaceutical wholesalers (who are parties who supply drugs to other parties, including the pharmaceutical traders themselves and retailers. Hospital/Clinic/Pharmacy/Drugstore) is a service facility provided by the government as a drug distributor to end consumers or patients. And most recently, consumers who use drugs later.

5.3. Data and Blockchain Technology blockchain

Transaction data that occurs during drug distribution in the pharmaceutical industry supply chain will be recorded into the blockchain system to ensure data can be stored safely and adequately and accessed by parties tied to this drug distribution network.

Figure 6: Pharmacy distribution model with blockchain [30]

Figure 7: Transaction model distribution of pharmaceutical drugs with blockchain [30].

- Timestamp, which is when the block is created in
- UNIX time, which is the number of seconds that it has
- applies when the block is formed.
- Distribution data, namely the number of distribution processes carried out on each party.
- Node ID, namely the identity of the node, which is the public key of existing nodes.
- Prev. Hash is the hash of the previous block.

5.4. Aspect in the pharmaceutical industry

The drug distribution process needs to be maintained and controlled to provide good quality drugs and in accordance with the standards set by the government. This can meet the health and safety of the community. For this reason, this quality can be maintained with a guideline for good drug distribution based on Regulation of the Drug and Food Supervisory Agency Number 9 of 2019 concerning Technical Guidelines for Good Drug Distribution Methods [4] including:

1. Quality Management.

The quality system developed must be completely documented and monitored for its effectiveness. There must be a control system in the system changes covering the principles of quality risk management.

2. The organization, management, and personnel.

Implementation and management of a good quality management system as well. The correct distribution of drugs and/or drug substances is very dependent on the personnel who run it. There must be sufficient and competent personnel to carry out all tasks responsible for the distribution facility. Management must appoint a person in charge of the distribution facility. According to the laws and regulations, the person in charge must be a pharmacist who meets the qualifications and competencies. The pharmacist who gets delegation is obliged to report the activities carried out to the person in charge. The person in charge has duties, including:

3. Buildings and equipment.

Buildings and equipment to ensure the protection and distribution of drugs and/or medicinal substances. Buildings shall be designed and adapted to ensure that good storage conditions are maintained, have adequate safety, sufficient capacity to allow proper storage and handling of drugs, and that storage area are equipped with adequate lighting to enable all activities to be carried out accurately and safely.

4. Operations.

All actions taken by distribution facilities must ensure that the identity of drugs and/or medicinal ingredients is not lost. Their distribution is handled according to the specifications listed on the packaging. Distribution facilities must use all available devices and methods to ensure that the source of drugs and/or drug

ingredients received comes from the pharmaceutical industry and/or other distribution facilities with licenses in accordance with statutory regulations to minimize the risk of drugs/or counterfeit drugs ingredients. Enter the official distribution chain.

5. Self-inspection

Self-inspection must be carried out to monitor implementation and compliance with CDOB compliance and follow up on necessary corrective steps.

6. Complaints on drugs and or returned drug ingredients, suspected to be fake and withdrawn.

All complaints and other information about potentially defective drugs should be collected, reviewed, and investigated according to written procedures. The responsible personnel must approve drugs to be resold in accordance with their respective authority.

7. Transportation.

The transportation process must apply adequate transportation methods. Medicines must be transported under storage conditions according to the information on the packaging. Appropriate transportation methods should be used, including transportation by land, sea, air, or a combination of the above. Whatever transportation is chosen, it must ensure that the drug does not undergo changes in conditions during transportation, which can reduce quality. A risk-based approach should be used when planning transportation routes.

8. Facility-based on the contract.

All contract activities must be in writing between the contract giver and contract acceptor, and each activity must comply with the CDOB requirements.

9. Documentation.

Good documentation is an important part of a quality management system. Written documentation should be clear to prevent oral communication errors and facilitate tracing, among other things, batch history, instructions, and procedures.

6. Conclusion

This study analyzes the application process of blockchain technology in the pharmaceutical industry in the distribution process. The process carried out shows that the application of blockchain technology helps the process carried out in the process of drug distribution carried out from the pharmaceutical industry (drug warehouse), which is distributed to distributors and retailers to consumers. Blockchain helps record all transactions that occur from related parties. Transactions that are recorded will be ensured by the characteristics of the blockchain, namely immutable, distributed, and ensuring data security from irresponsible attacks. With another guarantee from blockchain technology, there is traceability of transactions that occur. After developing a good drug distribution model with blockchain, we will build a prototype to prove the model described can be used by the pharmaceutical industry.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The aim of this study is, on the one hand learn about this type of wood, and on the other hand, is to study the processes the thermophysical characterization of araucaria wood from the city of el Jadida, Morocco, and on the other hand, will study the processes related to evaporation. Wood is defined industrially as an anisotropic and heterogeneous material formed over many years of a tree's life. The anatomical study of wood generally involves the examination of three directions of reference, the axial, radial and tangential directions. And a study of the constituent elements of wood being oriented in several directions, it follows from experience that its thermal properties differ in the longitudinal, radial or tangential direction, where thermophysical tests are carried out at wood moisture contents between 10 and 11%. Concerning the thermal properties, study highlighted, the determination of thermal conductivity, specific heat, thermal diffusivity and then the thermal effusivity of araucaria wood at different temperatures: 25°C, 35°C, 50°C and 60°C. The results are obtained experimentally by a device called "CT-Metre". He illustrated that this kind of wood is more conductive of heat in the longitudinal direction than the radial and tangential directions. Also, have determined the evaporation rate under well determined conditions, chose an enclosure to keep the set temperature, and then add NaCl to keep humidity at 75%, which also gives important results.

1. Introduction

This type of wood called Araucaria is one of the three genera of plants in the Araucariaceae family. This type comes from its name in the region of Araucania " Arauco " in Chile where two species of this type originate. The araucaria is also called " Chilean pine ". It has been around for several years. Fossil remains indicate that during the Mesozoic period they were abundant in the southern hemisphere [1].

Araucaria tree (Figure 1.) resembling pine trees with leaves in needles or triangular scales giving them a very special appearance. It was previously very popular as a decorative tree in public or

www.astesj.com

<https://dx.doi.org/10.25046/aj060231>

private gardens in Europe. In addition, the Araucaria fir is a large tree, with a straight trunk and very spreading low branches, which can reach more than 60 m in height in its natural state. The diameter of the trunk will hardly exceed 1.50 meters, its average density at 12%: 490 kg / m³ [2, 3]. In this article have treated the thermophysical properties such as thermal conductivity, specific heat per unit of volume, thermal diffusivity, thermal effusivity, this characterization done at different temperatures (25°C, 35°C, 50°C and then 60°C) and then determine humidity on the wood sample called " Araucaria ", the sample of a rectangular sizing (79.37×77.66×82.10 mm) . Also determined the evaporation rate on a small piece of a rectangular sample of wood with a surface section of (S = 6.25 cm²) and (h = 5 cm) in height, the sample are

first well dried in an oven at temperature 60 °C until the weight is normalized. The impregnations are applied to bare test tubes. They are placed perpendicularly on the grid, in a tank at the bottom of which the level of distilled water is kept constant throughout the duration of the experiment. The measurements of the thermal characterization part were obtained by a CT-Metre device at the Laboratory of Thermodynamics - Energy, Energy Center, Faculty of Sciences, Mohammed V University, Rabat, Morocco. The device used allows the thermal conductivity and specific heat to be determined experimentally in accordance with standard NF EN 993-15 of 2005. In addition, in our team are interested in thermal characterization of materials: wood, concrete, ceramic, etc. [4- 11].

Figure 1: a) Araucaria tree, b) Araucaria samples

2. Assembly presentation

To measure the thermal conductivity of a material is effected by conductimeter using a device “CT-metre” linked by accessories such as probes solid materials (using ring probe) and liquids (using wire probe) In order to allow us to evaluate thermal conductivity and specific heat volume. A glove box made up of a thermocouple which is used to fix the temperature and an interface which couples the assembly with a computer in order to display and examine the digital measured values.

The CT-Metre (Figure 2.) device, easily transportable, was to make calculations in order to allow to evaluate with precision, the thermal properties of a certain number of materials, such as: powdered substances, bitumen, earth, cellular concrete, rocks, complex products or resins, brick.

The mechanical and electrical properties of the control unit:

- Power delivered for the ring probe: 0 to 2.5 W
- Heating time: 400 s
- Measure time: 500 s
- Resistance: 2.5 ohm
- Dimension of the cabinet: 400 * 145 * 260 (mm)
- Weight of the box: 8 Kg
- Mains power supply: 230Vac / 50-60 Hz

The ring probe consists of a flexible printed circuit (0.2 mm thick - 60 * 90 mm), which is intended to be inserted between two flat pieces of the sample to be measured (their surfaces have been corrected beforehand).

The glove box plays a role in preserving the temperature variations of a sample in our case the wood sample (Araucaria), the latter composed of three materials linked to each other and each giving their function is the following: a contact thermometer which regulates the requested temperature, burning light bulbs during launching of the sample in the glove box to heat the sample then a fan which stirs the heat in the box.

Figure 2: Launch of Araucaria samples in CT-Metre device

3. Development of the experiment and drying kinetics

When the samples are at their saturated porosity, the evaporation experiments are carried out at the end of the capillarity experiment. They are packaged in neoprene bags so as to leave the upper face in contact with the ambient environment. The seal is reinforced with Teflon tape. These test specimens are placed to dry in a hermetically sealed enclosure: they are rectangular parallelepiped, with dimensions of 30 cm high, 40 cm long and 35 cm wide. Inside, a double cover located 5 cm from the bottom, limits the upset of the medium during openings, which is necessary for the weighing of the test pieces (Figure 3).

The experiment is applied in an enclosure whose air is conditioned where the temperature is kept constant is 22, and in which a brine maintains the medium at a constant relative humidity. In our experiment chose the NaCl salt which gives a relative humidity of 75% under the conditions of our experience. Scales are then run regularly until constant sample weight. The tank is hermetically closed, which makes it possible to maintain a humidity close to saturation and to cancel the superposition of evaporation phenomena.

Figure 3. Diagram of an enclosure used for the drying tests

4. Results and interpretation

4.1. Thermal conductivity

Table 1: Experimental values of thermal conductivity as a function of temperature at different temperatures of a sample of a three-sided araucaria

Direction	25°C	35°C	50°C	60°C
Longitudinal	0,314	0,318	0,333	0,352
Radial	0,219	0,219	0,227	0,242
Tangential	0,192	0,196	0,205	0,229

From Table 1, can plot a thermal conductivity profile by software as a function of different temperatures of a wood specimen of the genus araucaria in three directions:

Figure 4: Thermal conductivity at different temperature for the three-way araucaria sample

Can see in Figure 4, which displays the variation of thermal conductivity according to different degrees of temperature indicating this type of wood called araucaria, that the thermal conductivity is higher on the longitudinal axis than the other radial and tangential axes hence this type of wood is a heat conductor in the axial direction (Longitudinal).

4.2. Volume specific thermal heat

Table 2. Experimental values of specific heat by volume (KJ / m³.K) as a function of the temperature at different temperatures of the sample of three-sided Araucaria

Direction	25°C	35°C	50°C	60°C
Longitudinal	1564	1559	1697	1767
Radial	844	844	870	927
Tangential	780	818	890	1113

From Table 2 can plot by software a specific thermal profile for each unit volume at different temperatures of araucaria wood specimen on the three directions:

Figure 5: Experimental effect of temperature on the specific heat state of a sample of three-sided Araucaria

It can be seen from Figure 5 which presents the profile of the specific heat by volume per unit of volume at different degrees of temperature on the araucaria sample, that the a specific heat by volume per unit of volume is higher at a given temperature of 60 °C on the longitudinal axis of the other two radial and tangential axis, it almost degrades following the heat.

4.3. Thermal diffusivity

Thermal diffusivity characterizes the speed of heat propagation by conduction in a material, it depends on thermal conductivity, and the specific heat volume of a given material [13]: $D = \lambda / C$

With: C (J/K.m³), the following semi-experimental values of thermal diffusion D (m²/s) are thus obtained.

Table 3: The experimental values of thermal diffusivity as a function of temperature at different temperatures of a sample of three-sided Araucaria

Direction	25°C	35°C	50°C	60°C
Longitudinal	2,00E-07	2,03E-07	1,96E-07	1,99E-07
Radial	2,59E-07	2,59E-07	2,61E-07	2,62E-07
Tangential	2,46E-07	2,39E-07	2,30E-07	2,05E-07

Figure 6: Thermal diffusivity at different temperature in the case of Araucaria sample on three faces

From Table 3, can use software to plot the variation in thermal diffusivity at different temperatures for the araucaria wood sample on the three axes:

It can be seen from Figure 6 which shows the thermal diffusivity according to different temperature bottoming out (25°C, 35°C, 50°C and 60°C) applied to the sample of araucaria wood, it is observed that thermal diffusivity is higher on the radial axis than the other two tangential and longitudinal axis.

4.4. Thermal effusivity

The thermal effusivity of a material characterizes its ability to exchange thermal energy with its environment. It is expressed by the following relation [14-17]: $E \text{ (J/m}^2 \cdot \text{K} \cdot \text{s}^{1/2}) = \sqrt{\lambda \rho c}$

From this relation obtain the following semi-empirical values for the thermal effusivity $E \text{ (J/m}^2 \cdot \text{K} \cdot \text{s}^{1/2})$ the measurements given in Table 4.

Table 4: Semi-empirical results of thermal effusivity as a function of temperature at different temperatures for three-sided Araucaria sample

Direction	25°C	35°C	50°C	60°C
Longitudinal	7,01E+02	7,04E+02	7,38E+02	7,89E+02
Radial	4,30E+02	4,35E+02	4,49E+02	4,84E+02
Tangential	3,87E+02	4,00E+02	4,14E+02	4,57E+02

From Table 4, can use software to plot the variation in thermal effusivity at different temperatures for the araucaria wood sample in the three directions.

Figure 7: Thermal effusivity at different temperature in the case of a three-sided Araucaria sample

It can be seen from Figure 7, shows the thermal effusivity on the temperature according to different degrees of temperature, for the wood of araucaria, that the thermal effusivity increases on the longitudinal axis of given temperature of 60°C equivalent to 7.89E + 02 (J / m².K.s¹/²) than the other two radial and tangential axes.

4.5. Humidity level

To measure humidity be accomplished by relation (I.1), after taking steps such as weighing in an analytical balance and drying in an oven for at least 72 hours so that the mass remains stable.

First measure the mass of the araucaria sample (m_h). After drying, the anhydrous mass (m_0) is calculated, and the humidity or water content is expressed by the following expression:

$$H_u = \frac{m_h - m_0}{m_f} \times 100 \quad (1)$$

From the numerical calculation, get the moisture content of our studied sample is given in Table 5. These samples were studied in rectangular shapes, each sample is divided into two, and then proceed to heat treatments in the 'oven at 40°C for 72 hours to reduce the water content.

Table 5: Humidity level of the araucaria sample

Mass (g)	Dimension (mm)			Humidity (%)		Density (kg/m³)
	R	L	T	Dry	Raw	
320.50	79.37	77.66	82.10	10,79	9,73	633.399

From the measurements in Table 5 derive Figure 8:

Figure 8: Humidity profile for araucaria wood

Evaporation of the araucaria sample

Table 6: Drying kinetics measured on the araucaria sample after capillary saturation under 75% relative humidity, a temperature of 22 °C and without air agitation.

Relative humidity	Flux	Critical saturation	Saturation time critique
H.R 75%	F (g.cm².h⁻¹)	S _c (%)	t _{sc} (h)
araucaria	-2,2.10-3	76,4	140

According to Figure 9 which shows the evaporation kinetics curve of the araucaria sample at 75% relative humidity (HR), sample 5 cm high and 6.25 cm² of surface, can decompose this curve in three stages, the first stage which is linear has a constant flux $F = -2.2.10^{-3} \text{ g.cm}^{-2} \cdot \text{h}^{-1}$ and has a critical saturation time (t_{sc} (h)) 140 h, the critical saturation in this sample is 76.4%, from the point S_c beginning second stage Which is characterized by a curve not straight, by a flow decreases with time, and then the third stage its curve is linear has a very weak flow constant which vanishes over time.

Figure 9: Evaporation kinetics curve of the araucaria sample at 75% relative humidity, test tube 5 cm high and 6.25 cm² in area

5. Conclusion

After this thermal characterization study as well as the drying on the sample of araucaria wood from source the city of el Jadida, Morocco, conclude on the one hand that the thermal conductivity and also the specific heat per unit volume is increased at a temperature of 60°C on the longitudinal direction than the other two axes radial and tangential which indicates that this kind of wood is heat conductive on the axial axis (longitudinal), and on the other hand can summarize the results of wood drying in three parts, firstly, the evaporation rate (F1) is stable, (S_r) depends on the relative humidity, the weight loss is constant but should be negligible.

Nomenclature

H.R.: Relative humidity (%)
 F: Flux (g.cm⁻².h⁻¹)
 S_c: Critical saturation (%)
 t_{sc}: Critical saturation time (h)
 H_u: Humidity expressed in (%)
 m_h: Mass of the wet sample (Kg)
 m₀: Mass of the sample after conservation in the oven (Kg)
 λ: Thermal conductivity of the material (W m⁻¹ K⁻¹)
 ρ: The density of the material (kg m⁻³)
 c: The thermal mass capacity of the material (J kg⁻¹ K⁻¹)
 E: Thermal effusivity (J / m².K.s^{1/2})
 D: Thermal diffusivity (m²/s)
 C: Volume specific thermal heat (J / K. m³)

Just Walk Out Technology

Smart Shopping

JD.ID X Mart

Self Service Retail

ABSTRACT

This paper aims to measure the acceptance level of Indonesian customers to JD.ID X retail and to reveal the driving factors of behavioral intention to shop at the retail. JD.ID X is new retail that implements a new shopping technology called Just walk-out technology (JWOT) also known as retail without a cashier. JWOT is one of the latest innovations in the retail business that draws the authors intention as with this technology the shopping experiences becomes more efficient, effective, and enjoyable. We, therefore, examine some constructs related to this characteristic which are then classified as utilitarian and hedonic motivation. The method used in collecting data for this research is by distributing questionnaires through the Google form. Data is analyzed using Smart PLS 3.2.9. The results of this study indicate that there is a significant direct effect between automation, security/privacy risk, hedonic motivations on behavioral intention to shop at JD.ID X Mart. On the other hand, trust and utilitarian motivations do not have a significant direct effect on the dependent variable. Another finding is that, whilst trust does not mediate automation to the dependent variable, hedonic motivation shows a significant intermediating role between automation and the behavioral intention to use.

1. Introduction

1.1. The development of the retail industry in Indonesia

Retail is an important chain in the process of distribution of goods and is a chain in a distribution process. Through retail, a product can meet directly with its consumers. Based on data from the Indonesian Retail Entrepreneurs Association (Aprindo), the value of modern retail sales in 2016, 2017, and 2018 reached Rp205 trillion, Rp212 trillion, and Rp233 trillion, respectively. Whereas in 2019 modern retail sales are estimated to reach Rp256 trillion or grow by around 10% from last year's realization [1].

The modern market is the main driver of the development of modern retail in Indonesia. In 2004 - 2008, Modern Market turnover grew by 19.8%, the highest compared to other modern retail formats. Turnover of Department Stores, Specialty Stores, and other modern retail formats increased by only 5.2%, 8.1%, and 10.0% per year [2].

Progress in the economy has contributed to the development of modern markets and retail businesses in Indonesia. The growth of the middle class in the country encourages increased investment

interest and a passion for shopping. The World Bank states the number of middle-class populations in Indonesia in 2010 amounted to 56.5% of the total population. This figure has increased sharply compared to 1999 data when the number of middle class in Indonesia was estimated at 25% of the total population [3].

The retail network in Indonesia is currently growing, especially with the existence of modern retails. As a consequence, the rivalry between the retailers is also growing. Retailers do not want to just stand idly as a place to sell goods from other manufacturers. Many retailers are enthusiastic about creating innovations in shopping at their retail. One of them is a breakthrough in the retail industry which is retail without a cashier which is also known as Just walk out technology (JWOT). This technology combines the power of artificial intelligence (specifically machine learning in computer vision) that can track what items are taken on the shelf.

This shopping technology makes everyone shop calmly, without having to queue long at the cashier. Because all transactions are done automatically. Amazon Go in the United States is one of the retail of this kind. In Indonesia, in the year 2019, JD.ID X Mart a retail chain under PT. The National Joint

*Corresponding Author: Annisa Safira Braza, safirabraza@yahoo.com

Retail group was launched implementing the technology and business process similar to Amazon Go.

This research aims to examine customer's acceptance of the technology and retail in Indonesian context. The authors conducted a preliminary survey by interviewing several visitors at the JD.ID X Mart store. From this preliminary study, it was revealed that two main factors responsible for the people willing to use these services, namely IT and non-IT factors. The IT factor includes the implementation of the latest technology in Artificial Intelligence techniques such as face recognition and RFID technology that result in customers feel more effective and efficient shopping. As for the non-IT factor, the customer feels comfortable shopping at JD.ID X Mart because the price offered is also relatively cheaper than other retail stores, the location of JD.ID X Mart is in a shopping center that is easy to access from any part of Jakarta.

1.2. JD.ID and JD.ID X Mart

JD.ID is an e-commerce owned by a company PT. National Joint Retail and operates in Jakarta, Indonesia. JD.ID develops the mission of "make the joy happen", which is to bring happiness to all customers in Indonesia by providing reliable, fast, and safe services to choose a range of original quality products at competitive prices.

JD.ID's business is growing very rapidly. The number of products offered grew rapidly from less than 10,000 SKUs in 2015 to around 100,000 SKUs at the end of 2016. JD.ID also provides shipping services that reach 365 cities throughout Indonesia with thousands of fleets ready to deliver directly to JD.ID customers. According to iPrice's report, JD.ID is ranked 6th out of the top 10 e-commerce sites in Indonesia [4].

Toko Online	Pengunjung Baru Bulanan	Ranking Aplikasi	Ranking Website	Twitter	Instagram	Facebook	Google+
1 Tokopedia	168,200,000	#1	#1	162,230	1,028,990	6,028,100	2,215
2 Bukalapak	114,000,980	#2	#2	168,610	384,460	2,410,200	2,275

Figure 1: Largest E-Commerce in Indonesia During Q4 2018 (Source: iPrice)

Seeing the rapid development of e-commerce on Figure 1, this makes e-commerce always create innovations for the benefit of the community. That is what e-commerce JD.ID does. E-commerce JD.ID announced that it has presented a retail shop technology operating without cashier in Indonesia called JD.ID X Mart. As the most sophisticated retail store in Indonesia, JD.ID X Mart comes by offering a futuristic shopping concept with the support of artificial intelligence (AI). In this shop, consumers can experience shopping by utilizing various advanced technologies such as face scanners, radio-frequency identification (RFID), and non-cash payment methods. The products offered are available exclusively at JD.ID X also comes with special prices and consists of various popular products, including the fashion category for men and women, cosmetics, accessories and beauty, non-

electronic household products, and daily needs. Here is the process to shop at JD.ID X Mart as can be seen on figure 2:

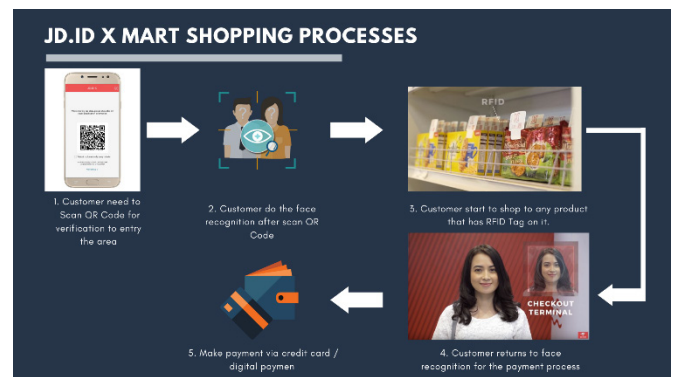

Figure 2: The processes of JD.ID X Mart

2. Literature Review

2.1. Just Walk Out Technology

Just walk out technology is an expression of smart shopping technology where the technology can automatically detect when a product is taken off the shelf and when the product is returned to the rack and can track the product in a virtual cart. When we have made the payment, we can just leave the store. This self-checkout shopping technology offers various kinds of expertise in shopping and makes shopping more effective and efficient.

The biggest reason for customers to use self-checkout machines themselves is because of the ease of payment and payments become more effective and efficient. Some people don't want to interact with cashiers and prefer to scan their items. In short, this technology has been attractive to the community.

With the development of technology, retailers are always developing innovation to create a new technology to make it easier for people to shop. One of them is just to walk out of technology innovation. There are many technological functions of this just walk out technology such as:

- **Sensor Fusion**

The fusion sensor is a method of combining two different types of sensors that have almost the same characteristics to get a new function. One function of sensor fusion is to get a comparison between two combined sensors.

- **Deep Learning**

Deep learning is another type of Machine Learning, it is inspired by the function of our brain cells called neurons that lead to the concept of artificial neural networks (ANN). Just walk out technology is one example of deep learning. Other examples of the application of deep learning are face recognition, human speech recognition and translation (google translate by voice), driver assistance.

- **RFID Tag**

RFID or can also be called Radio Frequency Identification is a wireless-based identification machine that allows data retrieval

without having to touch such as a barcode or magnetic card. This tool uses an electromagnetic radiation engine to transmit codes.

• Computer Vision

Computer Vision is how a computer/machine can see. Computer vision is a field that includes methods for obtaining, processing, analyzing, and understanding visual data such as images and videos. The main purpose of Computer Vision is that the computer or machine can mimic the perceptual abilities of the human eye and brain, or even be able to outperform it for certain purposes

2.2. Related Works

This research was conducted at retail stores that have a shopping process similar to Amazon Go. The author in [5] conducted a research to identify the main features of the stores, and interview to some Amazon Go users and staffs to reveal the factors that motivate someone to use the channel. The shopping experience is designed for those who don't like it standing in the payment line. Profits go to Amazon by eliminating check out personnel. Advanced technology tracks their purchases, allows them to leave the store without a physical check-out, and automatically withdraws a certain amount of money from pre-registered accounts. This paper also reports on the results of the author's interviews with several visitors. One relevant finding is that nearly all respondents agree that the automatization implemented by Amazon go brings many benefits and convenience to their shopping experience.

The researcher in [6] attempts to find hedonic and utilitarian motivational indicators that can influence UK wholesale consumers to adopt and use proposed new features of mobile applications in stores. The results of the study support that utilitarian motivation to shop for groceries includes time convenience, performance expectations and information availability. For hedonic motivation, the attributes supported include idea motivation, personalization, value motivation and experiential shopping.

The author explore the same problem, namely understanding the factors that encourage buyers to shop at a JWOT retail in Thailand similar to [7]. From this study, it is found that the original constructs derived from the TAM model significantly influence the desire to shop at the retail. Researchers also found that perceived entertainment value, trust, and technology anxiety do not have a significant role in the decision to use the JWOT.

Utilitarian and hedonics motivation in shopping has also been examined by [6]. In their paper the authors emphasized the utilitarian elements of efficiency, personalized services and convenient operation process were shown to be the dominant factors.

The effect of smart technology to customer dynamics and customer experience has been also be investigated by [8]. Their findings show that the commitment to learn plays a critical role to explain the behavioral intention, customer participation, customer dynamics and customer experience.

The researcher in [9] employed an extended IS success model to investigate the failure of self-service technology implementation. The author found that the individual technology anxiety and the need for the personal interaction became major factors affecting the technology acceptance.

3. Methodology

3.1. Research Model

In this study we used a combination model taken from the paper "User acceptance of smart home services: An extension of the theory of planned behavior" on figure 3 and "An In-Store Mobile App for Customer Engagement: Discovering Hedonic and Utilitarian Motivations on figure 4

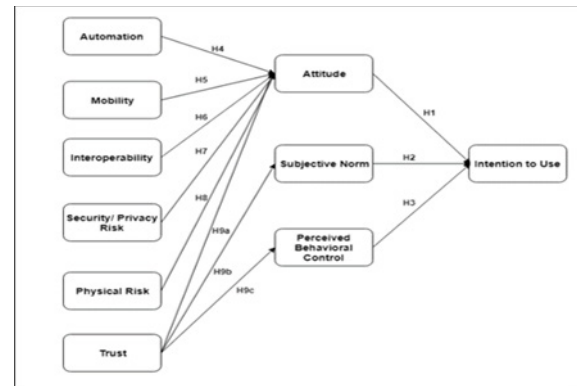

Figure 3: Paper research model "User acceptance of smart home services: An extension of the theory of planned behavior"

Figure 4: Paper research model "An In-Store Mobile App for Customer Engagement: Discovering Hedonic and Utilitarian Motivations".

The reason for combining the two models of the paper is because according to the results of the initial interview with the user/consumer of JD.ID X Mart is that the user/consumer wants to shop at JD.ID X Mart due to IT factors and non-IT factors. Examples of IT Factors are from the Artificial Intelligence technology side and the security system application. While examples for non-IT factors are users/consumers feeling happy shopping at JD.ID X Mart, feeling shopping at JD.ID X Mart can save more time. Therefore we adopt the model of the two paper models. After looking at each of the variables in the two models, some indicators do not match the model obtained from these two papers. For the Mobility, Interoperability, and Physical Risk variables, we don't use these variables because these variables are not by this study. The definition of Mobility and Interoperability is a system/application that can be done anywhere and can be remote anywhere. Humans have control/control of the system. Whereas in this research, the JD.ID X application can only be accessed and controlled when entering the JD.ID X Mart store and the customer has no control over the application. For Physical Risk this means

that the possibility of smart home users can endanger themselves or others. This is not following this study because shopping at JD.ID X Mart is not dangerous because the customer only interacts with JD.ID X system and application. Therefore, the writer re-modifies the model for the removal of several indicators so that it becomes a model like the picture below:

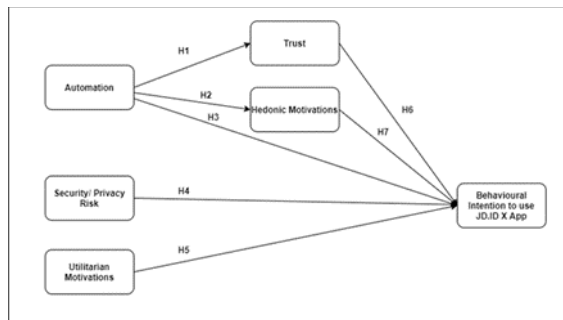

Figure 5: Research Model

As seen on figure 5, the hypotheses in this study include:

H1: Variation Automation has a significant effect on the variable Trust in shopping at JD.ID X Mart.

H2: Variable Automation has a significant effect on the Hedonic Motivations variable in shopping at JD.ID X Mart.

H3: Variable Automation has a significant effect on Behavioral Intention to use JD.ID X App in shopping at JD.ID X Mart.

H4: The Security / Privacy Risk variable has a significant influence on the Behavioral Intention to use JD.ID X App variable in shopping at JD.ID X Mart.

H5: Utilitarian Motivations Variable has a significant influence on the Behavioral Intention to use JD.ID X App variable in shopping at JD.ID X Mart.

H6: Trust variable has a significant influence on Behavioral Intention to use JD.ID X App in shopping at JD.ID X Mart.

H7: The Hedonic Motivations variable has a significant effect on the Behavioral Intention to use JD.ID X App variable in shopping at JD.ID X Mart.

H8: Trust variables have a significant mediating role between the Automation variables and the Behavioral Intention to use JD.ID X App.

H9: Hedonic Motivations has a significant mediating role between the Automation variables on Behavioral Intention to use JD.ID X App.

H10: Trust and Hedonic Motivations together have a significant mediating role between the Automation variable on Behavioral Intention to use JD.ID X App.

The questionnaire was made using a Likert scale with interval types. This Likert scale relates to statements about someone's attitude towards something, such as agreeing or disagreeing, happy or not happy, and good or not good. On a Likert scale, each item scale has five categories, namely "strongly disagree" to "strongly agree". To run the analysis, each statement is given a numerical score, ranging from 1 to 5, as follows:

2 = disagree

3 = Quite Agree

4 = Agree

5 = Strongly Agree

To determine the number of samples in the study, the authors used the Slovin formula. From the calculation of the Slovin formula above it can be concluded that the minimum number of samples in this study is a total of 400 samples.

This paper running data in 2 ways, namely the outer model and the inner model. Outer models are done by testing convergent validity, discriminant validity, and reliability testing. Convergent validity tests can be seen with the outer loading value and AVE (Average Variance Extracted). Discriminant validity test can be assessed by cross-loading. While the reliability test can be assessed with the Cronbach's alpha value. The inner model is done by testing R2 and Path Coefficient.

3.2. Operational Variable (Question of questionnaire)

Here are the questions to collect the data to conduct this study:

Table 1: Question of questionnaire

No	Construct	Item No.	Indicator
1	Automation (ATM)	ATM1	I feel comfortable shopping at JD.ID X Mart because the technology services provided allow me to actively shop without human intervention.
		ATM2	Using artificial intelligence technology at JD.ID X Mart makes shopping less complicated.
		ATM3	The Artificial Intelligence technology at JD.ID X Mart makes shopping even more time-saving.
2	Security/ Privacy risk (SPR)	SPR1	I don't feel worried about shopping at JD.ID X Mart by using the JD.ID X application because of its strong security system.
		SPR2	I do not feel any personal data leak when shopping using JD.ID X.
		SPR3	I feel that internet hackers (hackers) cannot control my payment account data

1 = Strongly disagree

No	Construct	Item No.	Indicator
			when shopping using the JD.IDX application.
3	Trust (TRS)	TRS1	I feel that JD.ID X Mart's AI technology services are reliable.
		TRS2	I feel confident when using JD.ID X Mart's AI technology services.
		TRS3	I feel JD.ID X Mart's AI technology services can meet my expectations in shopping.
		TRS4	I believe the products and services offered by JD.ID X Mart are of high quality
4	Utilitarian Motivations (UMT)	UMT1	Using the JD.ID X application when shopping in a store makes shopping activities less time-consuming.
		UMT2	Using the JD.ID X application makes me shop according to my shopping preferences.
		UMT3	Using the JD.ID X application when shopping at JD.ID X Mart allows me to access relevant product information.
		UMT4	Shopping at JD.ID X Mart makes the shopping process complete faster.
5	Hedonic Motivations (HMT)	HMT1	Shopping at JD.ID X Mart is an adventure for me.
		HMT2	I enjoy shopping at JD.ID X Mart using the JD.ID X application.
		HMT3	I feel happy when I manage to shop at JD.ID X Mart
		HMT 4	I feel proud to be able to shop at JD.ID X Mart
6	Behavioural Intention (BIT)	BIT1	I find it useful to shop at JD.ID X Mart.
		BIT2	I'm planning to shop at JD.ID X Mart in the near future
		BIT3	I predict that I will be shopping at JD.ID X Mart in the coming month.

No	Construct	Item No.	Indicator
		BIT4	I intend to do some shopping at JD.ID X Mart in the months to come.
		BIT5	I will recommend to my friends to shop at JD.ID X Mart

4. Result and Discussion

4.1. Respondent Profile

In this part of the respondent's profile, the author will display respondents in terms of demographics based on gender, age range, type of work, intensity of respondents shopping at JD.ID X Mart and from where respondents received information on the store JD.ID X Mart.

a. Profile of Respondents by Gender

Based on the results of the questionnaire collection on figure 6, it can be seen that the highest number of respondents is female gender as many as 203 respondents (55%), while respondents with male gender are 169 respondents (45%).

Figure 6: Respondents by Gender

b. Profile of Respondents Based on Age Range

Based on the collection of questionnaire results on figure 7, it can be known that based on age range, the highest number of respondents is 21-29 years old with 156 respondents (42%). While respondents with an age range of 30 - 39 years were 84 respondents (23%), an age range of 18-20 years were 73 respondents (20%), an age range of 40 - 49 years were 47 respondents (12%), age range 50 - 59 years as many as 12 respondents (3%) and no respondents from the age range of more than 60 years.

Figure 7: Age Range

c. Profile of Respondents by Type of Employment

Based on the collection of questionnaire results on figure 8, it can be known that based on the type of work, the largest number of respondents is the type of work of private employees, which is 160 respondents (43%). While respondents with the type of work as students were 148 respondents (40%), the type of work as a civil servant were 30 respondents (8%), 18 respondents (5%) did not work and 5 types of jobs as traders were traders (4%).

Figure 8: Type of Employment

d. Shopping intensity at JD.ID X Mart

Based on the results of the questionnaire collection, it can be seen on figure 9 that from the intensity of shopping at JD.ID X Mart, the number of respondents is the highest with the intensity of shopping at JD.ID X Mart, which is the respondent who only 1 times in a month shopped at JD.ID X Mart with 237 respondents (64%). While respondents with shopping intensity at JD.ID X Mart 2 to 5 times in a month were 119 respondents (32%), respondents with shopping intensity at JD.ID X Mart were more than 5 to 10 times in a month as many as 8 respondents (2%). And respondents with shopping intensity more than 10 times in a month as many as 8 respondents (2%).

Figure 9: Shopping intensity

e. Profile of Respondent by Get Store Information Sources

Based on the collection of questionnaire results on figure 10, it can be seen that based on JD.ID X Mart store information, the highest number of respondents gets JD.ID X Mart store information from social media (Instagram, Twitter, Facebook, etc.) with 205 respondents (55%). While respondents get JD.ID X Mart store information from print media (newspapers, magazines, brochures, posters, etc.) as many as 8 respondents (2%), respondents get JD.ID X Mart store information from electronic media (television, radio, internet, etc.) as many as 73 respondents (20%), respondents get store information JD.ID X Mart from verbal information (family, friends, relatives, relations, etc.) as many as 74 respondents (20%), and respondents get store information JD.ID X Mart went straight from his shop because he

happened to pass the JD.ID X Mart stores as many as 12 respondents (3%).

Figure 10: Type of information

The model testing is carried out with two steps, namely the measurement model (outer model) and the structural model (inner model). The outer model is done to test the validity and reliability of a model, while the inner model is done to predict the relationship between latent variables. Here are the structural models formed using Smart PLS.

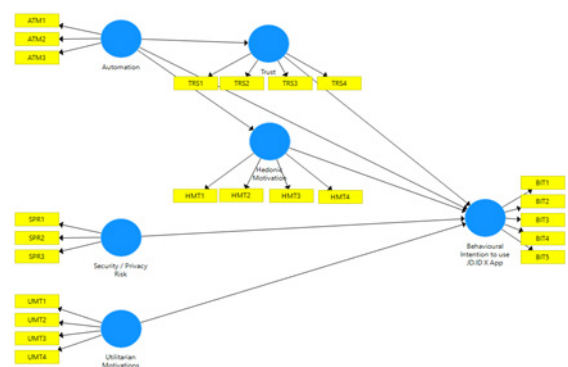

Figure 11: Research Model

4.2. Test Convergent Validity with Loading Factor

As seen on Table 2, In this loading factor, 2 indicators are removed, namely BIT3 and UMT3, because they have a factor value that is smaller than 0.7.

From the results of the loading factor above, it can be seen that:

- The ATM 1 indicator (active without human intervention) has the greatest influence on variable automation with a value of 0.902
- The BIT 1 indicator (the value of benefits in shopping) has the greatest influence on the behavioral intention variable to use the JD.ID X application with a value of 0.887.
- The HMT2 indicator has a great influence on the hedonic motivation variable with a value of 0.865.
- The SPR2 (system security) indicator has the greatest influence on the security / privacy risk variable with a value of 0.882.
- e) TRS1 indicator (believe in using) has the greatest influence on the trust variable with a value of 0.888.
- f) The UMT4 indicator (fast oriented process) has the greatest influence on the utilitarian motivation variable with a value

of 0.903.

Table 2: Loading Factor

Number of Questionnaire	Automation	Behavioral Intention to use JD.ID X App	Hedonic Motivation	Security / Privacy Risk	Trust	Utilitarian Motivations
ATM1	0.902					
ATM2	0.878					
ATM3	0.821					
BIT1		0.887				
BIT2		0.855				
BIT4		0.869				
BIT5		0.879				
HMT1			0.823			
HMT2			0.865			
HMT3			0.831			
HMT4			0.823			
SPR1				0.867		
SPR2				0.882		
SPR3				0.839		
TRS1					0.888	
TRS2					0.887	
TRS3					0.770	
TRS4					0.793	
UMT1						0.868
UMT2						0.823
UMT4						0.903

4.3. AVE

Based on the results of the AVE value shown on Table 4 by SmartPLS 3.2.9 as in the table above, it can be concluded that all question items are valid because they have an AVE value greater than 0.50 [10].

Table 3: Loading Factor

Construct	AVE
Automation (ATM)	0.753
Behavioral Intention to use JD.ID X App (BIT)	0.762
Hedonic Motivation (HMT)	0.698
Security / Privacy Risk (SPR)	0.745
Trust (TRS)	0.699
Utilitarian Motivations (UTM)	0.749

4.4. Crossloading

From the results of cross loading on table 4, it is known that each cross loading value of the indicator on its own construct is greater than the cross loading of other construct indicators, so it can be said that the questionnaire indicator is valid.

Table 4: Crossloading

	ATM	BIT	HMT	SPR	TRS	UTM
ATM1	0.902	0.749	0.755	0.628	0.721	0.720
ATM2	0.878	0.739	0.707	0.619	0.737	0.696
ATM3	0.821	0.528	0.531	0.471	0.637	0.684
BIT1	0.731	0.887	0.785	0.616	0.712	0.657
BIT2	0.597	0.855	0.685	0.578	0.580	0.558
BIT4	0.652	0.869	0.735	0.626	0.611	0.574
BIT5	0.747	0.879	0.813	0.579	0.701	0.702
HMT1	0.599	0.662	0.823	0.472	0.588	0.536
HMT2	0.714	0.805	0.865	0.603	0.687	0.671

HMT3	0.722	0.715	0.831	0.584	0.687	0.658
HMT4	0.538	0.706	0.823	0.500	0.507	0.481
SPR1	0.594	0.653	0.585	0.867	0.648	0.541
SPR2	0.580	0.581	0.601	0.882	0.588	0.505
SPR3	0.550	0.533	0.490	0.839	0.561	0.516
TRS1	0.695	0.613	0.652	0.583	0.888	0.721
TRS2	0.746	0.705	0.698	0.593	0.887	0.817
TRS3	0.551	0.489	0.470	0.526	0.770	0.564
TRS4	0.685	0.669	0.638	0.623	0.793	0.602
UMT1	0.739	0.647	0.643	0.558	0.758	0.868
UMT2	0.585	0.576	0.550	0.486	0.647	0.823
UMT4	0.758	0.635	0.642	0.521	0.711	0.903
UMT4	0.758	0.635	0.642	0.521	0.711	0.903

4.5. Cronbach's Alpha

Based on the results of the cronbach's alpha value on Table 5, it is known that each construct (Automation, Behavioral Intention to use JD.ID X App, Hedonic Motivations, Security / Pivacy Risk, Trust, Utilitarian Motivations) has high reliability or reliability because it has a value above 0.70 [10].

Table 5: Cronbach's Alpha

Construct	Cronbach's Alpha
Automation	0.836
Behavioral Intention to use JD.ID X App	0.896
Hedonic Motivation	0.856
Security / Privacy Risk	0.829
Trust	0.856
Utilitarian Motivations	0.832

4.6. R² Square

Based on the results of the R-square value in the table on table 7, it can be concluded that:

- The influence of Automation, Hedonic Motivations, Security / Privacy Risk, Trust and Utilitarian Motivations on Behavioral Intention to use JD.ID X App is 0.798. This means that the ability to influence the variables Automation, Hedonic Motivations, Security / Privacy Risk, Trust and Utilitarian Motivations to explain the Behavioral Intention to use JD.ID X App variable is 79.8%, while 20.2% is explained by factors other than this research.
- The effect of Automation on Hedonic Motivations is 0.602. This means that the ability of the influence of the Automation variable to explain the Hedonic Motivations variable is 60%, while 40% is explained by other factors outside of this study.
- The effect of Automation on Trust is 0.653. This means that the ability of the influence of the Automation variable to explain the Trust variable is 65.3%, while 34.7% is explained by other factors outside of this study.

Table 6: R2 Square

Construct	Cronbach's Alpha	Detail
Automation	-	
Behavioral Intention	0.798	High

to use JD.ID X App		
Hedonic Motivation	0.602	Average
Security / Privacy Risk	-	
Trust	0.653	Average
Utilitarian Motivations	-	

4.7. Path Coefficient

Path coefficient test is used to indicate whether there is influence between variables. If the greater the value of the path coefficient on one variable to another, the stronger the influence between these variables. To find out whether latent variables have a significant relationship or not, t-statistics or p values are used. In this study the authors used p-values.

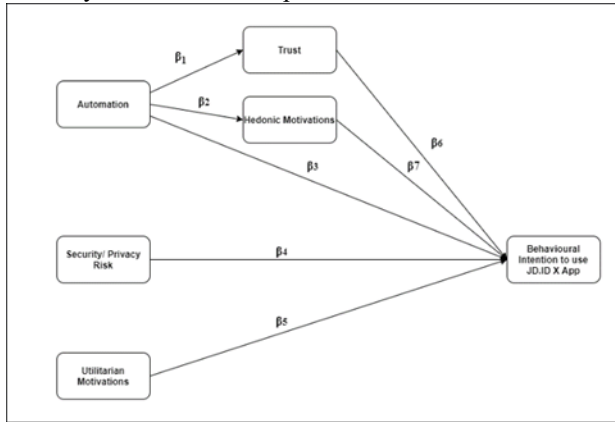

Figure 12: Path Coefficient

As seen on Figure 12, to see from the path diagram the path coefficient and the value of the path coefficient will be calculated based on the regression equation formula as follows:

$$\begin{aligned}
 \text{ME1} &= \text{I0} + \beta_1 \text{X1} + \epsilon_0 & (1) \\
 \text{ME2} &= \text{I1} + \beta_2 \text{X1} + \epsilon_1 & (2) \\
 \text{Y} &= \text{I2} + \beta_6 \text{ME1} + \beta_7 \text{ME2} + \beta_3 \text{X1} + \beta_4 \text{X2} + \beta_5 \text{X3} + \epsilon_2 & (3)
 \end{aligned}$$

If equation 1 and equation 2 are substituted for equation 3, the main equation is obtained:

$$\text{Y} = \text{I} + (\beta_3 + \beta_1 \text{B6} + \beta_2 \text{B7}) \text{X1} + \beta_4 \text{X2} + \beta_5 \text{X3} + \epsilon \quad (4)$$

4.8. Hypothesis Testing

Table 7: Hypothesis Testing

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (O/STDEV)	P - Values
Automation -> Trust	0,808	0,807	0,024	33,716	0,000
Automation -> Hedonic Motivation	0,776	0,776	0,024	32,759	0,000
Automation -> Behavioural	0,163	0,167	0,065	2,488	0,013

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (O/STDEV)	P - Values
Intention to use JD.ID X App					
Security / Privacy Risk -> Behavioural Intention to use JD.ID X App	0,135	0,133	0,041	3,312	0,001
Utilitarian Motivation -> Behavioural Intention to use JD.ID X App	0,056	0,054	0,060	0,921	0,357
Trust -> Behavioural Intention to use JD.ID X App	0,048	0,050	0,064	0,751	0,453
Hedonic Motivation -> Behavioural Intention to use JD.ID X App	0,578	0,576	0,070	8,263	0,000
Specific Indirect Effect					
Automation -> Trust -> Behavioural Intention to use JD.ID X App	0,039	0,040	0,052	0,750	0,454
Automation -> Hedonic Motivation -> Behavioural Intention to use JD.ID X App	0,448	0,447	0,055	8,194	0,000
Total Indirect Effect					
Automation -> Trust -> Behavioural Intention to use JD.ID X App	0,487	0,487	0,068	7,183	0,000

It can be concluded that overall the sample, 3 of the 10 proposed hypotheses were accepted. Hedonic Motivation and Trust are significantly influenced by Automation. Behavioral Intention to use JD.ID X App is significantly influenced by Automation, Hedonic Motivation, Security / Privacy Risk. Whereas Trust and Utilitarian Motivation do not significantly influence Behavioral Intention to use JD.ID X App. To see from the value of specific indirect effects, Trust does not have a significant mediating role between the Automation variable and the Behavioral Intention to use JD.ID X App variable, but Hedonic Motivations has a significant mediating role. And to see from the value of total indirect effect, Trust and Hedonic Motivations together have a significant mediating role between the Automation variable on Behavioral Intention to use JD.ID X App.

Here are the result:

- **Effect of Automation on Trust**

The first hypothesis shows that Automation has a significant effect on Trust. Hypothesis test results show that the t-statistics is **33,176**. This means that the Automation variable in terms of statistical calculations has a significant effect on Trust. Thus the first hypothesis is accepted.

The results of this study indicate that the greater the automation technology services provided at JD.ID X Mart for users / consumers, the higher the level of user confidence.

- **Effect of Automation on Hedonic Motivations**

The second hypothesis shows that Automation has a significant positive effect on Hedonic Motivations. Hypothesis test results show that the t-statistics is **32,759**. This means that the Automation variable in terms of statistical calculations has a significant effect on Hedonic Motivations. Thus the second hypothesis is accepted.

- **Effect of Automation on Behavioral Intention to use JD.ID X App**

The third hypothesis shows that Automation has a significant positive effect on Behavioral Intention to use JD.ID X App. Hypothesis test results show that the t-statistics is **2,488**. This means that the Automation variable in terms of statistical calculations has a significant effect on Behavioral Intention to use JD.ID X App. Thus the third hypothesis is accepted.

- **Effect of Security / Privacy Risk on Behavioral Intention to use JD.ID X App**

The fourth hypothesis shows that Security / Privacy Risk has a significant positive effect on Behavioral Intention to use JD.ID X App. Hypothesis test results show that the t-statistics is **3,312**. This means that the Security / Privacy Risk variable in terms of statistical calculations has a significant effect on Behavioral Intention to use JD.ID X App. Thus the fourth hypothesis is accepted. The results of this study indicate that the greater the value of security felt by users / consumers when shopping at JD.ID X Mart using JD.ID X App, the higher the value of people's intention to continue shopping at JD.ID X Mart.

- **The Effect of Utilitarian Motivations on Behavioral Intention to use JD.ID X App**

The fifth hypothesis shows that Utilitarian Motivations does not have a significant effect on Behavioral Intention to use JD.ID X App. Hypothesis test results show that the t-statistics is **0,921**. This means that the Utilitarian Motivations variable in terms of statistical calculations does not have a significant effect on Behavioral Intention to use JD.ID X App. Thus the fifth hypothesis is rejected.

The amount of benefit value in shopping at JD.ID X Mart does not in fact have an influence on the value of people's intention to continue shopping at JD.ID X Mart

- **The Effect of Trust on Behavioral Intention to use JD.ID X App**

The sixth hypothesis shows that Trust does not have a significant influence on Behavioral Intention to use JD.ID X App. Hypothesis test results show that the t-statistics is **0.751**. This means that the Trust variable in terms of statistical calculations does not have a significant effect on Behavioral

Intention to use JD.ID X App. Thus the sixth hypothesis is rejected. It can be concluded that the value of trust in shopping at JD.ID X Mart does not have an influence on the value of people's intention to continue shopping at JD.ID X Mart.

- **Effect of Hedonic Motivations on Behavioral Intention to use JD.ID X App**

The seventh hypothesis shows that Hedonic Motivations have a significant influence on Behavioral Intention to use JD.ID X App. Hypothesis test results show that the t-statistics is **8,263**. This means that the Trust variable in terms of statistical calculations has a significant effect on Behavioral Intention to use JD.ID X App. Thus the seventh hypothesis is accepted.

- **Effect of Trust Mediation between Automation on Behavioral Intention to use JD.ID X App**

The eighth hypothesis shows that the role of trust mediation between Automation and Behavioral Intention to use JD.ID X App does not have a significant effect. Hypothesis test results show that the t-statistics is **0.750**. That is, the role of Trust mediation in terms of statistical calculations does not have a significant effect between Automation on Behavioral Intention to use JD.ID X App. Thus the eighth hypothesis is rejected.

- **The Influence of Mediating Hedonic Motivations between Automation on Behavioral Intention to use JD.ID X App**

The ninth hypothesis shows that the mediating role of Hedonic Motivations between Automation and Behavioral Intention to use JD.ID X App has a significant effect. Hypothesis test results show that the t-statistics is **8,194**. This means that the mediating role of Hedonic Motivations in terms of statistical calculations has a significant effect between Automation on Behavioral Intention to use JD.ID X App. Thus the ninth hypothesis is accepted.

- **Effect of Trust Mediation and Hedonic Motivations between Automation on Behavioral Intention to use JD.ID X App**

The tenth hypothesis shows that the mediating role of Trust and Hedonic Motivations between Automation on Behavioral Intention to use JD.ID X App has a significant effect. Hypothesis test results show that the t-statistics is **7,183**. This means that the mediating role of Trust and Hedonic Motivations in terms of statistical calculations has a significant effect between Automation on Behavioral Intention to use JD.ID X App. Thus the tenth hypothesis is accepted.

5. Conclusion

From the results of research conducted and data processing that has also been carried out relating to any factors that influence people's behavioral intentions in shopping by using the JD.ID X application, here are the results: factors that do not significantly influence Behavioral Intention to use JD.ID X App in this study is Trust and Utilitarian Motivation. While the factors that significantly influence Behavioral Intention to use JD.ID X App in this study is Automation, Hedonic Motivation, Security / Privacy Risk. Factors that significantly influence Trust and Utilitarian Motivation in this study are Automation's factor.

From the results of the processed data, it can be seen that Automation does not significantly affect the Behavioral Intention

to use JD.ID X App, but the effect of Automation is stronger when mediated by the Hedonic Motivation variable, which means that the main motivation of people shopping at JD.ID X Mart not because of the Automation factor, but the Automation factor gives its value to Hedonic behavior. Which is the meaning of Hedonic behavior is that people feel the value of pleasure while shopping at JD.ID X Mart. So it can be concluded that people do not shop because the goal is to get the product they want or need or to find a better price, but people shop because there is motivation to increase their prestige, which is where self-esteem is increased when shopping at JD.ID X Mart.

In this study some factors are trust and utilitarian motivations have not been significant. It can be concluded that creating trust value requires interaction with a long time with a positive impression. And this can be proven by the answers of respondents' profiles with the intensity of shopping at JD.ID X Mart, it was noted that the highest value of respondents who had shopped at JD.ID X Mart was only one time, 237 respondents (64%). And for the utilitarian motivation factor, where the meaning of the utilitarian value is the community feels the value of benefits in shopping, in this study it can be concluded that the value of utilitarian motivation is not significant, it can be seen that the main purpose of the community in shopping at JD.ID X Mart has not been to look for the needs they want or look for the products they need because now the purpose of the community in shopping at JD.ID X Mart is because the automation factor is mediated by the hedonic factor itself. And this can also be seen from the respondents' answers if people feel the value of benefits (utilitarian motivation) in shopping at JD.ID X Mart, then for the value of shopping intensity at JD.ID X Mart should be the highest value that does not refer in "just 1-time shopping".

After seeing the results of this study, the authors see that initially, the automation factor can affect the behavioral intention of JD.ID X application users in shopping at JD.ID X Mart, but after seeing the results of this study it turns out that automation has not become a major factor in influencing behavioral intention in using the JD.ID X application but the hedonic motivation factor is the main factor in influencing the behavioral intention of JD.ID X application users to shop at JD.ID X Mart.

The suggestion for the future management of JD.ID X Mart is that the manager must also increase the value of utilitarian motivations and trust, not just automation. Because the automation value will sooner or later be followed by existing competitors. For how to increase it can be increased from the product being sold, make the item the main attraction, create value that consumers who shop want to find the goods they need as well, and good goods. Because based on the data obtained, the reason people shop at JD.ID X Mart is not because of that. To increase the value of trust, managers must also increase trust with various marketing strategies, so that fanatical customers will shop.

Authors believe that the results of future research with expanding the scope and adding aspects to the research model will produce theoretical and practical implications that are useful for industry and people who frequently shop at JD.ID X Mart using JD.ID X.

ABSTRACT

Rated a high-risk cyber-attack type, Advanced Persistent Threat (APT) has become a cause for concern to cyber security experts. Detecting the presence of APT in order to mitigate this attack has been a major challenge as successful attacks to large organizations still abound. Our approach combines static rule anomaly detection through pattern recognition and machine learning-based classification technique in mitigating the APT. (1) The rules-based on patterns are derived using statistical analysis majorly Kruskal Wallis test for association. A Packet Capture (PCAP) dataset with 1,047,908 packet header data is analyzed in an attempt, to identify malicious versus normal data traffic patterns. 90% of the attack traffic utilizes unassigned and dynamic/private ports and, also data sizes of between 0 and 58 bytes. (2) The machine learning approach narrows down the algorithm utilized by evaluating the accuracy levels of four algorithms: K-Nearest Neighbor (KNN), Support Vector Machine (SVM), Decision Tree and Random Forest with the accuracies 99.74, 87.11, 99.84 and 99.90 percent respectively. A load balance approach and modified entropy formula was applied to Random Forest. The model combines the two techniques giving it a minimum accuracy of 99.95% with added capabilities of detecting false positives. The results for both methods are matched in order to make a final decision. This approach can be easily adopted, as the data required is packet header data, visible in every network and provides results with commendable levels of accuracy, and the challenges of false positives greatly reduced.

1. Introduction

Information security challenges have been of great concern to Information Technology (IT) experts. These challenges involve the use of malicious techniques to get unauthorized access in an attempt to disrupt service, steal information and inflict harm amongst others [1] and [2]. The effect of a successful attack has moved from just affecting machines to posing a risk to human existence and wellbeing. In 2014, 7.2 million US dollars was the estimated cost of an attack to an organization [1]. In [3], the estimated annual cost of cyber security breaches for 2015 was 3 trillion US dollars and estimated to rise to 6 trillion by 2021.

In 2009, Advanced Persistent Threat (APT) a relatively new cyberattack method named based on its traits, was discovered and has been a serious cause for concern to information security experts. Advanced Persistent Threat's most accepted definition is the National Institute for Science and Technology's (NIST)

definition. NIST defined it as the use of multiple attack vectors to perpetrate targeted attacks by a well-skilled expert, exposed to huge resources. These targeted attacks negatively affect organizations through the exfiltration of confidential information, creating access for future attacks amongst others. This type of attack is successful due to the actors persistence, metamorphosis and obfuscation [4] and [5].

Advanced Persistent Threat (APT) thus refers to a targeted threat continually and gradually transforming through obfuscation methods and multiple attack techniques and vectors thereby granting an unauthorized user undetected access and control of the target systems for an extended period of time [6] and [7]. This threat majorly targeting the network plane but classified as a multi-plane threat, continually goes through metamorphosis and rapidly spreads while persistently attempting to infiltrate the target organization. Due to the rapidly increasing growth in the fields of computing and networking, APT is increasingly drawing attention among security experts.

Gaining popularity in the first half of 2011 due to the high level of attacks to well-known organizations, Advanced Persistent Threats (APT) cases show that huge organizations including the financial organizations, military, chemical plants, energy and nuclear industries, education institutions, aerospace, telecommunication, and governments. APT attacks that occurred in 2011 tagged by the malware utilized include; Red October, Aurora, Duqu, Ke3chang, RAS breach, Flame, Stuxnet, Snow Man, and Mini Duke amongst others [8] and [9].

Earlier studies on APT attacks aimed at identifying the inherent characteristics of APT, characterize APT attacks into phases and present generic countermeasures in an attempt to militate APT [10]-[12].

Citing the ease of penetration through APT attacks and the results of evaluative studies on these attacks show the difficulty in detecting and preventing APT attacks. The gravity of APT is visible from the occurrence of high profile APT attacks and the exfiltration of sensitive data from highly recognized organizations like Sony, Citigroup, RSA security, NASA, FBI, Fox broadcasting, etc. [7] Research shows that traditional methods for securing data were used in these organizations, but the attacks were still executed un-prevented. Researchers have pointed out and scrutinized this challenge, which is to a great extent related to the failure in preventing and detecting targeted attacks using existing conventional techniques [13] and [14].

This failure has led to breaches involving confidential information and documents of organizations and government agencies. Existing methods have been ineffective in the fight against APT activities in the user, application, network and physical plane.

The continuing cases of these malwares bypassing existing security infrastructure, show that vulnerabilities and threats exist even in the midst of existing technical mitigation techniques. The solutions that utilized similar approaches suffered setbacks due to the occurrence of false positives.

This study is an extended paper titled “Mitigating Advanced Persistent Threats Using A Combined Static-Rule And Machine Learning-Based Technique” from the 15th International Conference on Electronics Computer and Computation (ICECCO) conference held in Abuja Nigeria in December, 2019 [15].

In this respect, this study proposes an ensemble anomaly detection technique combining static-rule based anomaly detection technique and an optimized ensemble machine learning algorithm. This study also assesses the efficacy of the proposed approach in mitigating APT attacks and reducing the occurrence of false positives. This approach provides a new easy mechanism for the detection and prevention of attacks to information systems.

2. Related Work

Mitigating Advanced Persistent Threats (APTs) has been a major concern for existing Intrusion detection and prevention systems. A lot of research work has been done in an attempt to provide a solution to APT like attacks. This section presents similar work done in militating the threat citing their success rates, effects and limitations.

In [12], [16]-[18] and proposed implementing traffic/data analysis using divergent techniques. This method was applied to detecting infected PDF and TIFF related files by [16] and

embedded exe files in [17]. The major shortcomings were time delay and the need for human intervention. In [18] and [12] the authors suffered setbacks as the financial resources needed were high when compared to the impact on eliminating the threat. In [19], the author proposed the use of additional features to an open-source Intrusion Detection System. Additional features include data traffic analysis to detect malicious activity based on the state of the packet in transit and the port used, blacklist filters and the use of hash algorithm in protecting the integrity and confidentiality of the data within an organization.

A gene-based technique using patterns in detecting APT was employed in [20]. This approach identifies similitude with APT attacks using patterns from previous attacks. In [20], the author utilizes a network protocol behavioral pattern to form a gene-based detection system.

This work focuses on combining static-rule based anomaly detection technique and machine learning-based technique. Table 1 presents machine learning-based approaches to mitigating Advanced Persistent Threats.

Table 1: Related Works

Author	Method	Accuracy
[3]	Machine Learning technique using correlation analysis	84.8%
[21]	Random Forest Algorithm	99.8%
[22]	Simple Vector Machine	98.6%

In [3], the author adopted machine learning techniques using correlation analysis in an attempt to mitigate Advanced Persistent Threats. The machine-learning algorithm collects the output of other detection methods and classifies the Advanced Persistent Threats alerts. The results in [3] showed an accuracy of 84.8% in classifying malicious versus normal. In [21], the author used random forest algorithm to predict and detect APT achieved 99.8% accuracy. Their work showed high accuracy in properly classifying data traffic. A dataset of 1228 log events classified using Support Vector Machine algorithm showed an accuracy level of 98.67% [22]. Several machine learning algorithms have been proposed and applied to mitigating APT, but the most common algorithms used with APT detection and prevention are majorly: Simple Vector Machine (SVM), K-Nearest Neighbor (KNN), Decision Tree and Random forest [3], [14], [23] and [24]. This narrows down the machine learning algorithms to four for this study. Machine learning approach unlike the other methods proposed, showed a high level of effectiveness in mitigating APT even without prior knowledge of the attack vector utilized. The major challenge with the machine learning approach is the occurrence of false positives, which can be misleading.

Having presented and discussed related approaches to mitigating Advanced Persistent Threats as well as machine learning-based approaches in mitigating Advanced Persistent Threats and citing their shortcomings, the next section presents details on the materials and methods approach to mitigating APT.

3. Materials and Methods

This section describes procedures to be used in investigating and finding a solution to the research problem. This section also

evaluates the reason and relevance for the recommendation and application of techniques in identifying, collecting and analyzing information and data used in mastery and comprehension of the research problem. Hence, proving that the outcome of the research work is reliable, valid and reproducible.

In completing the research objectives the method to be used is broken down into two parts:

- a. Static-Rule Based Anomaly Detection (Statistical Analysis).
- b. Machine Learning Based Anomaly Detection

Figure 1 shows the steps and their relationships involved in completing the research objectives. The research plan is explained as follows:

1. Research Goals: The first part identifying research goals, this has been outlined in section one. The goal is to mitigate Advanced Persistent Threats.
2. Data Collection: The data to be used is secondary data. The dataset is used with both methods highlighted above which include the Static-Rule Based anomaly detection utilizing statistical analysis and the machine learning-based stages consisting of three sub-stages. A dataset local to the physical location of the researchers was not available as Nigeria is yet to identify or document any successful APT attack. The dataset utilized was obtained from Coburg University located in Germany. The dataset consists of network packet metadata. This dataset was developed by tracking network packets and documenting header details. This dataset consists of 1,047,908 instances and identified as Coburg Intrusion Detection Dataset (CIDD) [25].
3. Statistical Analysis/ Static-rule stage: In generating rules to detect anomalies, patterns are identified that can be used to filter data traffic and properly classify them. The approach used in obtaining these patterns is by statistical analysis. The outcome of the statistical calculations provides the basis for the formation of rules guiding the static-rule based anomaly detection model. Static-rule based anomaly detection utilizes finite sets of rules in anomaly detection. ALGORITHM 1 presents the procedure in sequence for the detection process.

3.1. Algorithm 1

Input $V = (a_i, b_i)$ [metadata fields to be tested]
Output: malicious traffic,
 $P = \{p_1, p_2, \dots, p_n\}$ [Metadata collected, where T is metadata of all traffic within network]
Begin
 Initialize $P = \{ \} \in T$, $S = \{S_1, S_2\}$ [where S_1 and S_2 represents the margin to differentiate between normal and malicious]
 For each p_i where $\{a, b\} \subseteq P$
 $V \leftarrow \{a_i, b_i\}$
 For each $V (<, > \text{ or } =) S_1$, $V (<, > \text{ or } =) S_2$ and $V (<, > \text{ or } =) S_3$ [S_1 , S_2 and S_3 are predefined rules]
 If $D \leftarrow a_i = b_i$
 Return D
End

ALGORITHM 1 provides a step by step process for detecting APT using static-rule based anomaly detection. V is gotten from the network traffic through sensors that capture traffic data, where the $V i (a_i, b_i)$ is used to detect anomalies for instance i . The response to the procedure is the identity of the malicious traffic D . $P = \{p_1, p_2, \dots, p_n\}$ is a subset of the entire traffic of the network collecting data for some traffic within the network. The initialization stage resets P to empty and the margins for S_1 and S_2 are set. The values for a, b for each i gotten from the metadata of each packet. Conditions for identifying the malicious traffic $V (<, > \text{ or } =) S_i$ are checked and stored in $D \leftarrow a_i = b_i$. D is flagged as malicious traffic, and alerts the administrator of malicious activity.

The implementation conditions required for the adoption of Static rule-based anomaly detection is evident as illustrated using the algorithm above and is proved using a statistical test for association. The hypothesis used as the basis for this test are given below

4. Research Hypothesis

H_0 : There is no difference between normal and malicious traffic with respect to source port, destination port, packets and bytes.

H_1 : There is a difference between normal and malicious traffic with respect to source port, destination port, packets and bytes.

4. Machine Learning: This is the second phase of this work. It is also used to improve accuracy and for greater effectiveness by combining both methods. Machine learning uses characteristics similar to that of humans who react based on knowledge to respond to events. This ML stage consists of 3 sub-stages which are recursive.
 - a. Data Cleaning: Misleading and inconsistent data that may affect the effectiveness of the machine-learning algorithm was removed using WEKA 3.8.3. The data affected constituted 0.06% of the whole dataset. The affected rows were deleted as other methods will likely introduce bias.
 - b. Feature Selection: Determining the effect of each feature on the final results is of utmost importance. When features do not contribute or contribute negatively to the final outcome, deactivating them is very necessary. This stage deals with selecting features of positive effect in achieving higher accuracy in Mitigating APT. Using univariate selection method, feature selection through Extra tree classifier and correlation matrix, flows showed no positive effect in classifying anomalous versus normal traffic. The conclusion is based on the χ^2 score of 0.000000e+00 for the test of non-negative features see Figure 2, 0.00 score on the graph showing feature importance see Figure 3 and no correlation with other features see Figure 4.
 - c. Classification and testing for accuracy: Using four algorithms 80% of the dataset is used to train and 20% to test. The test is to check how well the algorithm can properly classify the instances of data so as to pick the most accurate and fastest. The best algorithm is optimized to improve its classification accuracy while checking instances of overfitting. These algorithms are: Simple Vector Machine, Random Forest, K Nearest Neighbor and Decision tree. Divergent methods are adopted by these algorithms in classifying events based on their similarities. The choice of these algorithms was based on the frequency of their utilization in APT like researches. [3], [14], [23] and [24].

Figure 3: Graph showing Feature Importance

- d. **Build Prediction Model:** The output of the classification stage is collected for developing the model. The algorithm selected is improved upon using load balancing due to the dataset distribution, as the instances of attack traffic are insignificant when compared to the instances of the normal traffic. The algorithm is also optimized using a trial and error approach.

- e. **SIEM Implementation:** The final stage combines both approaches of the static-rule based anomaly detection and the enhanced machine learning-based prediction model, implementable as an SIEM module using REST API as seen in Figure 5. This stage presents the proposed solution in an attempt to mitigate Advanced Persistent Threats. The SIEM tool was considered as this solution is being implemented widely in organizations and has the capability of adding new features.

Figure 4: Correlation Matrix for the Dataset

The Dataset, which is in PCAP (Packet Capture) format, is feed at the top of Figure 5 as network traffic. The choice of using PCAP files is as a result of the information contained being easily extractable from the packet header during data transmission. The dataset is duplicated to feed both sides of the model. One copy feeds the left side of the model while the second copy feeds the right side. The left side of the model takes the dataset and the features are filtered to collect the statistically relevant data for

analysis, this happens at the defining variables stage. Using statistical analysis test for association, patterns to be used as a threshold for a static rule detection model can be gotten. These thresholds are set using rules S_1, S_2, \dots, S_n depending on the number of distinct patterns. With defined thresholds, new data traffic can be filtered based on the rules. The results of the filtering process are presented for decision-making based on the two methods. The results from the static rule-based anomaly detection method are presented in percentages based on how many attack patterns the captured traffic matches.

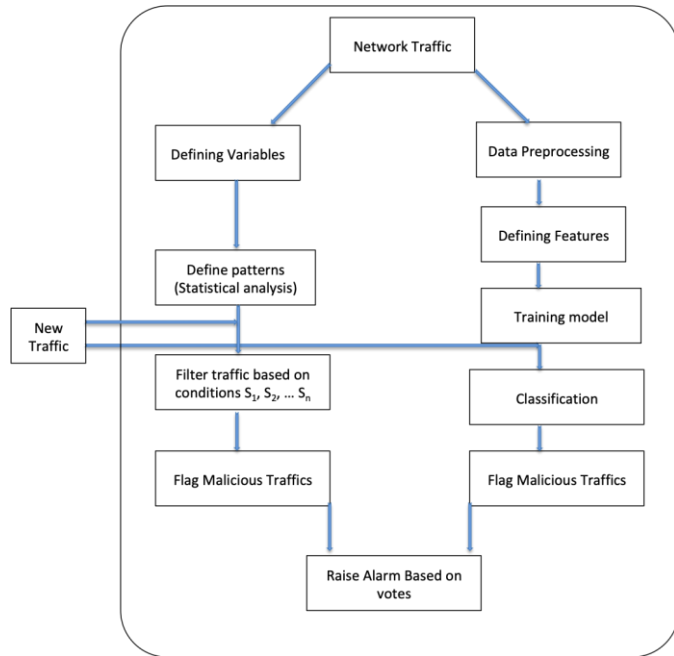

Figure 5: Proposed Model

The right side goes through the processes highlighted in 4 above. The three stages: data preprocessing/cleaning, feature selection and training the model are of importance to be able to accurately predict anomalous traffic. The model after these three stages can receive new traffic data and classify it accurately. The instance of the malicious traffic predicted is matched to the rule-based results to check if the results are true positives. The combination of static rule-based approach and machine learning is targeted towards reducing the occurrence of false positives.

5. Results

Finite set of patterns are obtained using Kruskal Wallis test for the implementation of static rule-based anomaly detection, following a normality test. Kruskal Wallis is a nonparametric test used to test for comparing k independent samples using population medians. The results are represented in

Table 2.

Table 2: Non-Parametric Test Results

Field	Median (Average rank Z)			Test statistic H	P-value
	Normal	Malicious (attacker)	Malicious (victim)		

Source	8082	51357	2701	2941.21	0.000
Port	(-27.27)	(50.56)	(-18.87)		
Packets	1.0	1.0	1.0	11357.29	0.000
	(98.14)	(-79.17)	(-63.76)		
Bytes	120	58	54	31357.13	0.000
	(173.47)	(-124.25)	(-121.05)		

- Source port:** $p\text{-value} < 0.05$. Reject H_0 . There is evidence that at least 2 of the medians are different. Furthermore, the overall mean rank is significantly higher than both the normal and victim Z values ($Z = -27.27 < -1.96$ & $Z = -18.87 < -1.96$), and the Overall mean rank is significantly lower than the Z value for attacker ($Z = 50.56 > 1.96$). From the results, there is significant evidence that the median port number for attacker is higher than that of normal and victim traffic.
- Packets:** $p\text{-value} < 0.05$. Reject H_0 . There is evidence that at least 2 of the medians are different. Furthermore, the overall mean rank is lower than the Z value for normal ($Z = -98.14 > 1.96$), and the overall mean rank is higher than the Z value for both attacker and victim traffic ($Z = -63.76 < -1.96$ & $Z = -79.17 < -1.96$). There is significant evidence to show that the median number of packets for attacker and victim traffic is lower than the median number of packets for the normal traffic.
- Bytes:** $p\text{-value} < 0.05$. Reject H_0 . There is evidence that at least 2 of the medians are different. Furthermore, the overall mean rank is lower than the Z value for normal ($Z = 173.47 > 1.96$), and the overall mean rank is higher than the Z value for attacker and victim traffic ($Z = -124.25 < -1.96$ & $Z = -121.05 < -1.96$). There is significant evidence to show that the median size in bytes for victim and attacker traffic is lower than that of normal traffic.

From the results in 1, 2 and 3, having discovered patterns in network traffic vital in distinguishing between normal, victim and attack traffic we have the following rules.

Rule 1 (S_1): Flag traffic with source port within the unassigned and dynamic/private ports range.

Rule 2 (S_2): Flag traffic if size in bytes is between 0 and 58.

Rule 3 (S_3): Temporarily block and flag traffic that matches both S_1 and S_2 .

The results from the statistical analysis done on the feature packets were dropped, as the results were not distinct. The predefined rules implemented in the static rule algorithm in section 3 number 3 to filter traffic and present suspicious traffic and match with the machine learning model results.

Having discussed the test results and highlighted rules based on patterns discovered for detecting malicious traffic, the machine learning approach and results of the modified Ensemble detection technique is presented.

The machine learning-based anomaly detection approach to militating APT attacks is due to the evidence that knowledge based on experience or previous events is of utmost importance in detecting mischievous activity without any interference.

Having prepared and cleaned the dataset, and selected the features to be utilized, the next phase is data classifying and accuracy and speed test. The algorithms to be used are all supervised learning techniques. Table 3 presents the results of the classification using four algorithms and the optimized ensemble algorithm for implementation in the model see Figure 2. The results are based on the accuracy in correctly matching instances and the time taken.

Table 3: Machine Learning Approach

S/No	ML Algorithm	Accuracy (%)	Time taken (Seconds)
1	K Nearest Neighbor (KNN)	99.74	693.34
2	Support Vector Machine (SVM)	87.11	359.95 (Dataset size 5,240)
3	Decision Tree (CART)	99.84	30.56
4	Random Forest (RF)	99.90	78.95
5	Optimized Random Forest	99.95%	(Dataset size 70,000)

Using KNN algorithm, the test data, which is 20% of the dataset set of 1048575 is 209582. The dataset consists of three classes namely: attacker, victim and normal traffic. The results show that 209037 of 209582 instances of data were properly classified. This gives a 99.74% accuracy.

SVM was initially unsuccessful in classifying due to the size of the dataset and would take an infinite duration of time in performing this task as the algorithm works better with small datasets. On reducing the size gradually to 5240 instances a classification using SVM was successful with an accuracy of 87.11% as seen in Table 3. This is done using a random function to select 0.5% of the instances randomly from the 1048575 dataset to remove fears of bias.

On using the Decision tree algorithm on the 1048575 dataset, the results from the confusion matrix and classification report provided by Scikit-learn showed that, 209246 instances out of 209582 were correctly classified. This gives a 99.84% accuracy. The RF algorithm gave an accuracy of 99.90%.

The RF Algorithm was selected and modified based on the high accuracy of 99.90% recorded. The modifications included load balancing of the dataset and modifying the formula for entropy. The justification for this approach was based on the fact that the dataset was unevenly distributed and also in an attempt to improve on the existing results as entropy provides the best conditions for splitting the trees. Algorithm 2 shows the load balance technique used.

5.1. Algorithm 2

Input:

```
train_df = (Duration, Src_pt, Dst_pt, Packets, Bytes, Tos,
Label),
n_trees=5,
n_bootstrap=70000,
n_features=4,
dt_max_depth=None
```

Output: Randomly selected datasets of size = n_bootstrap
Begin

For i in n_trees:

train_df1 = random select 200000 from train_df where

Label=Attacker with replacement

train_df2 = random select 200000 from train_df where

Label=Victim with replacement

train_df3 = random select 200000 from train_df where

Label=Malicious with replacement

train=train_df1+train_df2+train_df3

train= random select n_bootstrap from train with replacement

return train

End

From Algorithm 2, the CIDD dataset of size 1048575 is first broken down into 200,000 instances per label. The 3 labels providing a dataset of 600,000 randomly selected instances. This step evenly balances the dataset presenting 200,000 for Attacker traffic, 200,000 for Victim traffic and 200,000 for normal traffic. The dataset of size 600,000 is then reduced to 70,000 the bootstrap size per tree using random selection. The dataset of size 70,000 is used to build one tree in the forest. Data is selected randomly based on labels to load balance the dataset for each tree making the learning data better distributed. The second modification done on the algorithm is modifying the formula responsible for splitting the tree based on the best condition for a split. The calculation for entropy is presented in equation 1, and the modified formula in equation 2.

$$\text{Entropy} = -\sum p * \log_2(p) \quad (1)$$

The modified formula introduces a constant 10 as seen in equation 2.

$$\text{Entropy} = -\sum p * 10 * \log_2(p) \quad (2)$$

These two enhancements when implemented increases classification accuracy from 99.90% to 99.95% and also utilizing a smaller subset of 70,000 from the 1048575 dataset. The results in Table 4 show the decision-making table.

Table 4: Decision Making Table

Static- Rule algorithm (Careful or Jump)	Optimized Random Forest algorithm (Attacker, Victim or Normal)	Decision
Carefull (Malicious)	Attacker (Malicious)	Malicious
Jump (Normal)	Victim (Malicious)	Maybe
Jump (Normal)	Normal (Normal)	Normal

Storing the results of both algorithms in a data frame provides the platform in making a decision on whether to flag traffic or not. A conditional statement is applied to the data frame fields to make decisions based on the values from both fields. Table 4 provides a sample of results using a combined approach consisting of both static-rule based anomaly detection and machine learning techniques in mitigating APT.

6. Discussion

Mitigating Advanced Persistent Threats and reducing their effects to an acceptable risk level, has been an issue and threat to the existence of organizations, data as well as the safety of humans. The results from this study, show great accuracy levels and effectiveness using a hybrid approach comprising of both static and machine learning techniques in mitigating Advanced Persistent Threat attacks. The dataset utilized contains PCAP files classified into attacker, victim and normal traffic using divergent attack vectors per instance. These PCAP files hold packet metadata which is easily extractable by off the shelf and cloud applications like Wireshark and OpenStack. Following a hybrid anomaly detection approach, statistical analysis is used to test the dataset for association in the patterns using labels. The outcome indicated as shown in Table 3, that a high number of both the attacker and victim instances that are malicious, are often of a few bytes. Port numbers for attacker and victim traffic as also indicated in Table 3 often fall within the range of private/dynamic port numbers between 49152 to 65535. These patterns meet the requirements for implementing static-rule anomaly detection as they are finite. From algorithm 1, these rules can be implemented by replacing S_1, S_2, \dots, S_n with the conditions. This approach filters the data traffic and detects malicious activities labeling the traffic as either Jump(Normal) or Careful(malicious) as seen in Table 4. The aim is to combine two methods in an attempt to increase the accuracy level as well as reducing the chances of false positives thereby improving the effectiveness in mitigating APT. The combination of static rule anomaly detection with ML technique indicates positive results in greatly increasing the efficacy in the fight against APT as shown in section 4. The algorithm with the highest accuracy is picked based on the evaluation of multiple algorithms and considered the best algorithm for the prediction model using the PCAP dataset. The algorithms used are selected on their utilization in work done on mitigating APT. These algorithms when used on the PCAP dataset, also indicated a high level of effectiveness in mitigating APT attacks with 87.11%, 99.74%, 99.84% and 99.90% accuracy levels for SVM, KNN, CART and RF algorithm respectively as shown in Table 3. Choosing the algorithm with the best accuracy (RF) with the modifications applied increases the accuracy and effectiveness. The optimizing approach consists of dataset balancing and modifying the formula used in selecting the best point for tree branching. Accuracy increase from 99.90% to 99.95% is recorded after the modification, thereby improving the chances of effectively and accurately detecting APT attacks. Achieving a 99.95% accuracy in malicious traffic classification and a 90% chance of utilizing port numbers and bytes in detecting fraudulent traffic through static-rule based detection. The combination of these methods shows great results in providing highly accurate and an effective method in the detection, prediction and prevention of APT. This approach reduces false positives as the detection of APT traffic detected with both methods as shown in Table 4, proves that the threat is correctly identified (true positive) and hence the planned attack foiled. This result shows impressive effectiveness in mitigating APT when compared to the results in Table 2. This work leads [21], the best work also with 0.14%. Lower accuracies were recorded by the other algorithms. By this, our work provides the most effective method in mitigating APT besides the ability of the model to solve the problem of false positives. The outcome of the

four algorithms selected had commendable accuracy levels but with the improved accuracy level using the modified algorithm improved the effectiveness making this the best method in mitigating APT.

The results of the model cannot be lower than the highest accuracy level recorded by the machine learning component of the model and hence, the accuracy level for the optimized Random Forest algorithm marks the minimum accuracy level for the model tagged at 99.95%. Implementing this model also ensures a 90% chance in accurately detecting APT traffic (True positives). This approach will reduce the chances of attackers using this method for economic sabotage, destruction of organizations reputation and cyberwars.

7. Conclusion

APT attack exploits grow every year with improved levels of sophistication and obfuscation. The challenge in effectively detecting and preventing APT attacks against large organizations and governments introduces a great risk in the loss of confidential and valuable information and services. Having looked into prevention and detection techniques, combining and modifying existing approaches on their effectiveness as well as integrate new methods is needed. From studies done, Anomaly detection proved the most promising existing mitigation method although, challenges with false-positive results occasionally occur. This study proposes a behavioral pattern recognition approach using statistical analysis to create a static rule-based model in an attempt to limit the chances of false-positives and improve the model's effectiveness in mitigating APT. The proposed combined model of static-rule based detection and machine learning-based techniques with an optimized algorithm, showed increased accuracy in mitigating APT. The ability to detect malicious traffic in 90% of the network data traffic using the static rule approach and an accuracy of 99.95% in detecting malicious traffic utilizing machine learning approaches, presents an optimized ensemble model for mitigating APT with greatly manageable and reduced occurrence of false-positives. The prediction model has a minimum accuracy of 99.95%, which is the accuracy level of a single component of the model. From the results, this approach to APT will solve to a large extent the challenges of cyber security experts and their fears about Advanced Persistent Threats (APT). This work provides a model for mitigating APT, implementation in organizations, testing and improvements in handling false positives are areas for further work.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Effective Fetal Electrocardiogram (FECG) Extraction provides medical workers with precise knowledge for monitoring fetal health condition during gestational age. However, Fetal ECG Extraction still remains a challenge as the signal is weak and contaminated with noises of different kinds, more significantly maternal ECG. In this work, a new Moth Flame optimization algorithm (MFO)-based adaptive filter is proposed for the extraction of FECG signal. A noninvasive two-point method is used to record thoracic and abdominal ECG signals from the mother's body. The abdominal ECG (AECG) signal is made up of fetal heart signal, the distorted maternal heart signal and noise. The thoracic signal contains the undistorted maternal heart signal. The two signals are applied to an adaptive filter whose coefficients are optimally determined by the conventional least means square (LMS) algorithm and MFO. Simulation results using both synthetic signals and the real data from Physionet data base developed by MIT- BIH show the superiority of the new approach over conventional methods. The performance has been proven by observation of the quality of the extracted wave forms and quantitatively by computing the Signal to Noise ratio (SNR) which was 10.28 for proposed algorithm as compared to 0.1028 for the connectional LMS and mean square error (MSE) which was 0.0215 for the proposed algorithm as compared to 0.0275 for the convectional LMS. The results indicate that the new approach is suitable for Fetal Electrocardiogram extraction from AECG.

1. Introduction

FECG reflects electrical activity of fetal heart. It can be used to discover Fetal Heart Rate (FHR) and multiple pregnancies and to establish if the fetus is in distress. It is also useful in function parameter analysis of heart for the prevention of neonatal diseases [1]. The two methods used for obtaining FECG are the use of electrodes applied on the scalp of the fetus and through non-invasive recording by placing electrode on mother's abdomen. Invasive recordings achieve better quality but the process is regrettably difficult and only applicable during labor [2]. In contrast, the recording by noninvasive means has the advantage of being simple, noninvasive and can be applied throughout gestational period. That is why medical workers and pregnant women have deeply welcomed it [3].

The major drawback of noninvasive FECG (NI-FECG) recording is contamination with various forms of noise like maternal ECG (MECG), electromyogram (EMG), baseline wandering, power line interference, etc.[4], [5].

Research is ongoing on methods of extracting FECG from AECG. MECG is the most influential interference noise signal present in the AECG which has been suppressed using various techniques such as adaptive filters [4], [5] and wavelet transform [6]-[9] among other methods [9], [7]. Two things characterize adaptive filters. First, the type of unit sample response based on which we have Finite Impulse Response (FIR) and Infinite Impulse Response (IIR) filters. Second, the optimization algorithm used. Gradient-based optimization algorithms are popular, but they have the problem of convergence at local minimum for multimodal error surfaces [10]. Attempts to solve the problem of local minima and achieve global optimum solution has led many researchers to introduce the use of global optimization techniques for adaptive filter optimization such as Genetic Algorithm (GA) [11], Simulated Annealing (SA) [12], Tabu Search (TS) [13], Differential Evolution (DE) [14], Particle Swarm Optimization (PSO) [15], Ant-colony (ACO) [16], Artificial intelligence [17] Modified firefly and modified ABC algorithms [18].

In this work, LMS algorithm with its exploitation ability, robustness, ease of implementation, low computational complexity and unbiased convergence [19] is combined with MFO which has high global search (exploration) capability. MFO has the additional advantages of simplicity, flexibility and ease of implementation. Due to these advantages, it has been successfully applied in many optimization applications [20]. Some of these include scheduling [21], classification [22], power energy [23], medical [24], and image processing [25]. However, from available literature, this is the first time MFO is being used for FECG Extraction.

2. Fetal ECG Monitoring

Figure 1 illustrates the method of FECG monitoring. Two electrodes are placed on the body of a pregnant woman; one each on her chest and abdomen. Three signals are recorded by the electrode placed on the abdomen. One of them is the corrupted version of the maternal ECG (MECG) signal, i.e. $\hat{x}(n)$. The second is FECG signal $s(n)$ and the third is noise from various sources denoted as $\eta(n)$. Equations (1) to (3) describe the relationship between these signals.

$$A(n) = \hat{s}(n) + \hat{x}(n) \quad (1)$$

$$\hat{x}(n) = T(x(n)) \quad (2)$$

$$\hat{s}(n) = s(n) + \eta(n) \quad (3)$$

MECG as recorded by the abdominal electrode is corrupted due to the nonlinear transformation it undergoes as it travels from the chest to the abdomen.

Figure 1: Fetal ECG Monitoring

3. Proposed Extraction Algorithm

The proposed method of adaptive filtering as depicted in Figure 2 consists of two adaptation algorithms; the LMS alone and

LMS/MFO. These algorithms (implemented one after the other) were used to update the weights of Finite Impulse Response Filter based on the error signal (desired signal). Here the noisy abdominal signal is given as input and a thoracic electrode output signal is given as reference input to the filter. Since the signal of interest is the fetal heartbeat, maternal heart beat is considered as the interference noise to the signal. The primary signal is the fetal electrocardiogram measured from the abdominal electrode. It consists of mainly maternal heartbeat which dominates the fetal heartbeat and some residual measurement noises. The reference signal is taken from the chest of the mother through thoracic electrode which consists of actual maternal heart beat with some additive noise. Adaptation algorithm here uses the error signal as its input and updates the filter coefficients based on the parameters defined to the filter. The output obtained by the filter should be approximately equal to the noise i.e. the maternal heart beat in the primary signal so that the error signal obtained should be fetal heart signal. The error signal obtained finally corresponds to the fetal heart beat signal but corrupted with residual noises which are in turn eliminated by filtering them out adaptively.

3.1. Configuration of the Adaptive Filter

The configuration of the adaptive filter is shown in Figure 3. The filter is shown to be operating in time domain.

Abdominal Electrode (MECG + FECG + NOISE)

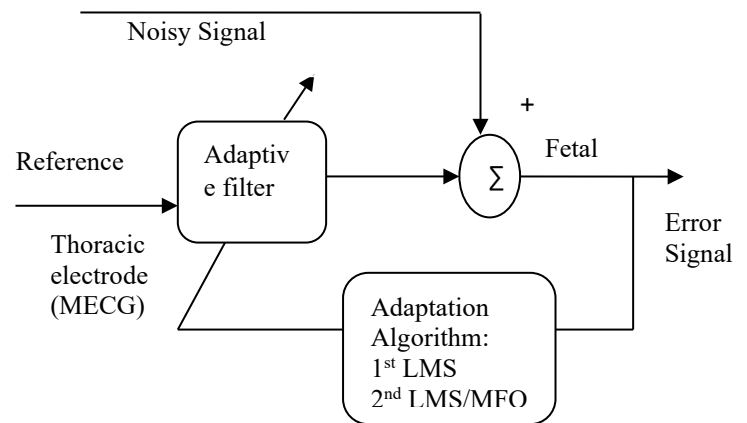

Figure 2: Block diagram of proposed algorithm

Figure 3: Adaptive filter structure

In Figure 3, $s(n)$ is the primary signal while the primary noise is $\eta(n)$, and the two are uncorrelated. $x(n)$ is the reference signal and it is strongly correlated with $\eta(n)$ but uncorrelated with $s(n)$. The output error $e(n)$ is given by

$$e(n) = s(n) + \eta(n) - y(n) \quad (4)$$

The error signal serves as the input to the adaptation algorithm [26]-[28] which subsequently adjusts the adaptive filter coefficient vector $W(n)$ depending on some measurements standard. The adaptation process is geared towards minimizing the error signal (in this case the fetal ECG).

According to [26]-[28], the mean square error (MSE) is a measure that shows how effectively a system adapts to a specified solution. The final value of MSE can be used to decide on proficiency of the adaptation algorithm. Consequently, a least value signifies the efficiency of the algorithm and in contrast, a high value normally signifies the inability of the algorithm to model the specified system or the initial state of the adaptive filter is inappropriate starting point to ensure the adaptive filter convergence. The mean square error is given by

$$e^2(n) = E[e^2(n)] = E[|s(n) + \eta(n) - y(n)|^2] \quad (5)$$

where $E[\cdot]$ indicates expectation operation. For noise cancellation, the goal is to have a system output best fit in the least squares sense of the signal $s(n)$. The mean square of error is of interest and can be obtained as follows

$$e^2(n) = s^2(n) + (\eta(n) - y(n))^2 + 2s(n)(\eta(n) - y(n)) \quad (6)$$

Taking expectation of both sides

$$E[e^2(n)] = E[s^2(n)] + E[(\eta(n) - y(n))^2] + 2E[s(n)(\eta(n) - y(n))] \quad (7)$$

Since $s(n)$ is uncorrelated with both $\eta(n)$ and $y(n)$

$$[e^2(n)] = E[s^2(n)] + E[(\eta(n) - y(n))^2] \quad (8)$$

Adapting the filter minimizes the mean square of error. This has no effect on the input signals(n).

$$\min [e^2(n)] = E[s^2(n)] + \min E[(\eta(n) - y(n))^2] \quad (9)$$

If the means square error is minimized, output of the filter, $y(n)$ will be a best least square match to $x(n)$. We can rewrite (4) as

$$(e(n) - s(n))^2 = (\eta(n) - y(n))^2 \quad (10)$$

Minimizing the mean square error of (10)

$$\min E[(e(n) - s(n))^2] = \min E[(\eta(n) - y(n))^2] \quad (11)$$

Minimization of the mean square error makes $e(n)$ to be the most suitable match of the signal $s(n)$ in the least squares sense. This is achieved by adaptive filtering with no a priori information about the signal and noise statistic.

3.2. Least Mean Square Algorithm

The popularity of LMS as an adaptive filter algorithm is due to its simplicity, robustness, ease of implementation, low computational complexity, stability and unbiased convergence as reported by [19]. From Figure 3

$$y(n) = W(n)X(n) \quad (12)$$

where $W(n)$ is a vector representation of the adaptive filter weights and $X(n)$ is a vector of the corresponding delayed values of $x(n)$ as depicted in Figure 3. That is,

$$y(n) = \sum_{i=0}^{N-1} w(n)x(n-i) \quad (13)$$

where

$$X(n) = [x(n), x(n-1), x(n-2) \dots \dots x(n-(N-1))] \quad (14)$$

and

$$W(n) = [w_0(n), w_1(n) \dots w_{N-1}(n)] \quad (15)$$

The estimation error, $e(n)$ is given by

$$e(n) = s(n) + \eta(n) - y(n) \quad (16)$$

and the weights are updated as follows

$$w(n+1) = w(n) + \mu e(n)x(n) \quad (17)$$

where μ is called the step-size, $w(n)$ represents the new coefficient values for the next time interval, $x(n)$ is the filter (reference) input signal, $y(n)$ represent the filtered output, $s(n)$ is the desired response and $e(n)$ is the error function. The convergence of $W(n)$ to the optimum solution and the convergence speed depend on the value of step-size parameter μ .

3.3. Moth-Flame Optimization Algorithm (MFO)

Moth-flame optimization (MFO) was initiated by Mirjalili in 2015 [29]. It is among the latest metaheuristic population-based methods. It is an optimization design to mimic the behavior of moth, a type of butterfly species flying in night towards a moon in a straight line known as transverse orientation for navigation. However, turn to spiral motion when encountered with shorter light source. Consequently, this led to the formulation of an interestingly new optimization algorithm. Additionally, MFO was designed to achieve exploration and exploitation goal as it combines population-based algorithm and local search strategy. Also, to prevent the solution being trapped in local minima, the optimal solutions were maintained in each repetition as reported in [29]. The algorithm uses the explorative as well as exploitative search to get an optimized solution.

In the introduced MFO, a moth is considered to be a candidate solution and the position of moth at different search space as problem's variables. Hence, the moth can fly in hyper dimensional space or 3D dimensions and changing their position vectors. Since MFO is population-based, matrix representation of the swarm of moths can be made as in (18)

$$MO = \begin{bmatrix} MO_{1,1} & \dots & MO_{1,D} \\ \vdots & \ddots & \vdots \\ MO_{N,1} & \dots & MO_{N,D} \end{bmatrix} \quad (18)$$

We can evaluate the fitness of each moth by means of the fitness function. The fitness is stored in a matrix as in (19)

$$O_{MO} = \begin{bmatrix} O_{MO_1} \\ \vdots \\ O_{MO_n} \end{bmatrix} \quad (19)$$

The matrix of (20) stores moths best positions in each dimension as flames, while the generated corresponding fitness values are stored as in (21).

$$FO = \begin{bmatrix} FO_{1,1} & \cdots & FO_{1,D} \\ \vdots & \ddots & \vdots \\ FN_{N,1} & \cdots & FN_{N,D} \end{bmatrix} \quad (20)$$

$$O_{FN} = \begin{bmatrix} O_{FN_1} \\ \vdots \\ O_{FN_n} \end{bmatrix} \quad (21)$$

The spiral movement of the moth around the flame is represented in (22)

$$S_{MO_i}, FO_j = |FO_j - MO_i| * e^{bt} \cos(2\pi t) + FO_j \quad (22)$$

here, S_{MO_i} , FO_j , indicate the spiral motion, b is a constant associated with the shape of the spiral movement. t is a random variable used to select the position of a moth from the flame. $t = -1$ represents the closest position while $t = 1$ represents the farthest position of the moth. Equation (22) is used to update the position of the moths with the best moth position updating the flame position. Furthermore, the number of flames is decreased in each iteration using (23)

$$NOF = \text{ceil} \left(N - C_{iter} * \frac{N-1}{T_{iter}} \right) \quad (23)$$

where ceil , C_{iter} and T_{iter} , denote round to whole number, the current iteration number and the total number of iterations respectively. MFO process is elucidated in Table 1.

MFO algorithm is illustrated in Table 1. The next stage describes the implementation of MFO in the proposed work.

Table 1: The MFO Process [29]

--

3.4. MFO Adaptive Filtering

It is noteworthy that we are using the moth flame optimization algorithm to optimize the LMS adaptive filtering algorithm. The moths here represent the filter coefficients to be updated. This means for each filter coefficient ($w(n)$), there is a moth and the position of the filter coefficient is considered as the position of the moth. This is because the moth is taken to be candidate solution in the search space and when the moth changes position, the filter coefficient is adjusted. The process continues repeatedly until the best coefficients are obtained as in MFO process in Table 1. The number of dimensions, $D = 3$ since the filter coefficients ($w(n)$) would be placed in a real world environment. The position matrix representing the moth based on filter coefficient ($w(n)$) is given by (24).

$$M_N = \begin{bmatrix} M_{N_{1,1}} & M_{N_{1,2}} & M_{N_{1,3}} \\ M_{N_{2,1}} & M_{N_{2,2}} & M_{N_{2,3}} \\ M_{N_{n,1}} & M_{N_{n,2}} & M_{N_{n,3}} \end{bmatrix} \quad (24)$$

here, n is a number representing the length of the coefficient vector ($W(n)$) in the network. The fitness value of the current filter coefficient ($w(n)$) is generated by using its distance from the destination. Equation (25) is used to generate the said fitness value.

$$M_{N_1} = \sqrt{(M_{N_{d,1}} - M_{N_{1,1}})^2 + (M_{N_{d,2}} - M_{N_{1,2}})^2 + (M_{N_{d,3}} - M_{N_{1,3}})^2} \quad (25)$$

The matrix of fitness values is as given in (26).

$$O_{MN} = \begin{bmatrix} O_{MN_1} \\ \vdots \\ O_{MN_n} \end{bmatrix} \quad (26)$$

The flame matrix gives the position matrix of the best neighbor filter coefficient ($w(n)$) to be selected in the route by any filter coefficient ($w(n)$) given by (27) and corresponding fitness value matrix generated using the (25) is given in the (28).

$$F_N = \begin{bmatrix} F_{N_{1,1}} & F_{N_{1,2}} & F_{N_{1,3}} \\ F_{N_{2,1}} & F_{N_{2,2}} & F_{N_{2,3}} \\ \vdots & \vdots & \vdots \\ F_{N_{n,1}} & F_{N_{n,2}} & F_{N_{n,3}} \end{bmatrix} \quad (27)$$

$$O_{FN} = \begin{bmatrix} O_{FN_1} \\ \vdots \\ O_{FN_n} \end{bmatrix} \quad (28)$$

The position of the filter coefficient ($w(n)$) to be selected next in the route is given by the (29).

$$M_{M_{iF_j}} = |F_j - M_i| e^{bt} * \cos(2\pi t) + F_j \quad (29)$$

The new position obtained using the (12) need not be the exact position of the filter coefficient ($w(n)$), so the filter coefficient ($w(n)$) nearest to the updated position is to be selected, so the (12) is applied to generate the matrix in (30).

$$D_{M_N} = \begin{bmatrix} D_{M_{N_1}} \\ \vdots \\ D_{M_{N_n}} \end{bmatrix} \quad (30)$$

For the updated matrix M_N to be generated, a quick sort can be performed on matrix D_{M_N} . The algorithm would then select M_N or F_{N_1} according to the fitness value. In other words, filter coefficients ($w(n)$) with lower fitness values (which are better) are selected. The estimation error is thus decreased to minimal value.

4. Simulation, Results and Discussion

4.1. Generation of Synthetic Signals

A sampling frequency of 4 KHz is used to simulate the maternal ECG shown in Figure 4. Other important parameters for the signal are the approximate heart rate of 89 bpm (beats per minute) and the peak voltage of 3.5 mV.

The FHR is normally higher than the maternal heart rate, with the former ranging from 120 bpm to 160 bpm. For the simulated FECG signal the heart rate is 139 bpm and the peak voltage is 0.25 mV. [30]

The signal obtained from the abdominal electrode is a noisy signal and is shown in Figure 6. This is to be filtered and given as input to the adaptive noise canceller.

The signal recorded by the thoracic electrode is given as reference signal [30] as shown in Figure 7. This is given as reference input to the adaptive noise canceller.

4.2. Simulation using Synthetic Signals

Figure 8 is the result obtained by training the adaptive noise canceller with LMS algorithm. In fetal ECG extraction QRS complex detection is important so that R-R interval and R peaks can properly be identified. In this case two R peaks indicated by arrows are poorly extracted that may hinder proper monitoring of fetal heart status.

Figure 9 to Figure 13: The results show that with moth population between 20 and 80, the first p-waves are missing or not clearly defined. However, all the waves were recovered and

R-R interval clearly seen when the moth population was increased to 100. Also, the expected FHR was equally recovered. The FHR was recovered using (31).

Figure 8: Result obtained by LMS

$$Hr = (rv * 60)/t \quad (31)$$

where rv is the R - R interval and t is the time interval.

Figure 9: LMS/MFO result at 100 moth pop.

Figure 10: LMS/MFO result at 80 moth pop.

Figure 11: LMS/MFO result at 60 moth pop.

Figure 12: LMS/MFO result at 40 moth pop.

Figure 13: LMS/MFO result at 20 moth pop.

Table 2 shows the results of magnitude of Mean Square Error (MSE) obtained at different moth population (between 20 and 100) at a fixed number of iterations. Table 3 shows the SNR before the application of the proposed technique and after. The SNR is calculated using (34).

$$SNR = 10 \log_{10}(P_s / P_n) \quad (34)$$

where P_s is the signal power, in this case the power of fetal ECG signal $s(n)$ which was obtained using $P_s = \text{var}(F1)$ and P_n is the noise power which represents the power of both deformed maternal ECG and white Gaussian noise. It was obtained using

$$P_n = \text{var}(N_t) \quad (35)$$

where var is variance of N_t (total noise),

$$N_t = \hat{x}(n) + \eta(n)$$

The result in Table 2 shows that the MSE is low with high population of moth (i.e. 100). The obtained mean square error values show that system has converted to a solution. Table 3 indicates a decrease of MSE and increase of SNR when the proposed algorithm was applied as required.

Table 2: Mean Square Error (MSE) Values at different Moth Population and fixed iteration number

Moth Pop	MSE	ITER
100	0.0215	20
80	0.0224	20
60	0.0224	20
40	0.0224	20
20	0.0224	20

Table 3: SNR and MSE for LMS and proposed LMS/MFO

Method	SNR	MSE
LMS	0.1028	0.0275
Proposed LMS/MFO	10.280	0.0215

Table 4 gives performance comparison of the proposed algorithm with conventional LMS and some existing methods. The proposed method shows improvement in SNR and decrease in MSE.

Proposed LMS/MFO	0.0215	10.280

4.3. Analysis Using Real ECG Signal

To establish the efficacy of the proposed approach a real abdominal ECG and thoracic ECG data were obtained from Physionet developed by MIT-BIH. Figure 14 and Figure 15 are the abdominal and thoracic ECG signals respectively. After the application of the proposed algorithm, Fetal ECG was extracted as

in Figure 16. The R peaks that are used to determine the FHR were efficiently localized.

Figure 14: Real abdominal ECG

Figure 15: Real thoracic ECG

Figure 16: Extracted fetal ECG

4.4. Performance Comparison with Existing Techniques

The results obtained using proposed LMS/MFO extraction method was compared with selected existing methods and the result is summarized in Table 4.

According to [34], actual comparison of the existing techniques for FECG extraction is still difficult due to the differences in dataset, evaluation techniques, etc used by individual researchers. It is thus easier to use specific criteria like improvement in SNR, computational complexity, etc. the following rather subjective criteria were proposed.

Overall performance: This has to do with the robustness of the technique. Performance can be classified as low, medium or high.

Low: Performance is classified as low when the technique is not suitable for FECG extraction but may be used to eliminate specific types of noise like power line interference, baseline wandering, etc. Low performance techniques are primarily capable of NI-FECG preprocessing.

Medium: In this case, techniques are suitable for advanced preprocessing. They are capable of removing most noise types in NI-FECG preprocessing. These include EMG, myopotentials, motion artifacts, among others. Medium performance techniques partly remove MECG thereby enabling the detection of FQRS (Fetal QRS) and consequently the determination of FHR.

High: High performance techniques are the strongest in terms of NI-FECG processing. A high performance technique supplies information on FHR and FECG morphology (PR, QT, ST, etc.).

Improvement in SNR: Like with overall performance, techniques are categorized into three (i.e. low, medium and high) in terms of SNR improvement. It is noteworthy that SNR accurately verifies proficiency of a technique with respect to some reference value. However, when it comes to clinical applications the use of SNR may not be very helpful. Techniques that show very high performance in the improvement of SNR may not be good in FQRS detection.

Computational Complexity: This is an assessment of the computational requirements of a particular technique. Computational complexity requirements may be high, medium or low. Of course, low is the best.

FHR (R-R): This is an assessment of the credibility of a technique under investigation in terms of its ability to determine FHR based

on R-R interval. Four classes are identified, viz. inaccurate, moderately accurate and very accurate.

Inaccurate: This is when a technique is not capable of effectively removing artifacts and noise for proper detection of the R-R interval. When an inaccurate technique is used to process NI-FECG, the result cannot be used for monitoring FHR.

Moderately accurate: This is when a technique effectively removes most common noises, thus enabling the detection of R-R interval. Of course, the noises are not effectively removed resulting in undetected and false-detected complexes. For moderately accurate techniques, maximum sensitivity is 80%, maximum PPV (positive predictive value) is 90%, maximum accuracy is 80% and probability of correct detection of beats (F1) is 85%.

Accurate: These techniques permit precise FHR detection. Maximum sensitivity is 85%, maximum PPV, 95%, maximum accuracy, 85% and maximum F1, 95%.

Very accurate: This class of techniques permits a very precise detection of FHR. For very accurate techniques, the maximum sensitivity is 95%, maximum PPV is 95%, maximum accuracy is 95% and maximum F1 is 95%. For values above this (say 99% PPV) a technique is still considered very accurate.

Morphological analysis (T/QRS; QT): This is a measure of the effectiveness of a technique being investigated for an in-depth analysis of the morphology of FECG. Three classes are identified.

Insufficient: When the quality of FECG extracted by a technique is not sufficient for morphological analysis.

Moderately accurate: This is when a technique allows for morphological analysis. The problem, in this case, is that SNR, age of gestation, position of fetus, etc. significantly affect the efficacy of the method except for some tested real data. Thus, for monitoring of T/QRS or QT interval, a moderately accurate technique cannot be used.

Promising: A promising technique has a very high potential of being used for morphological analysis.

Table 4: Comparison with some existing methods

Technique	Fetal Heart Rate, FHR (R-R)	Morphological Analysis (T/QRS; QT)	Overall Performance	Improvement in SNR	Computational Complexity
Wavelet Transform [35]	Moderately Accurate	Insufficient	Medium	Medium	Low
Independent Component Analysis [36]	Accurate	Moderately accurate	Medium	Medium	Medium
Singular Value Decomposition [37]	Inaccurate	Insufficient	Low	Low	Low
Sequential Total Variation Denoising [38]	Accurate	Insufficient	Medium	Medium	Medium
Template Subtraction [39]	Moderately accurate	Insufficient	Medium	Low	Low
Proposed Method	Very Accurate	Promising	High	High	Low

5. Conclusion

A new algorithm for FECG extraction has been presented. The algorithm which combines MFO algorithm and LMS adaptive filtering has two inputs, viz. the abdominal signal which is the major signal of interest and the thoracic signal which serves as the reference input.

The hybrid algorithm has been shown to be better than the LMS adaptive algorithm. Results have shown improvement in the detection of R-peaks of fetal ECG much better with 100 moth population. The superiority of the new approach has been shown quantitatively by MSE and SNR calculation.

A decrease of mean square error of 0.0215 was observed with the proposed algorithms and improvement of signal to noise ratio of 10.28 was also observed.

Comparison with existing methods shows better performance of the proposed approach.

Further research should focus on applying this method for multifetal ECG separation and the use of statistical method of analysis e.g. anova method for comparison of result.

Digital transformation

ABSTRACT

This paper describes a qualitative research design adopted in this study guided by deployment of a Grounded Theory (GT) methodology which was deployed to synthesize literature on technology adoption and digital transformation with an objective of developing theory. The philosophical worldview adopted was interpretivism/constructivist of a qualitative grounded theory inductive (theory building) approach where secondary data was sourced from industry reports and related academic peer reviewed literature. The grounded theory method was used to synthesize data which resulted in emergent dimensions that underpin digital transformation and technology adoption in the postal sector in the context of Southern Africa. The careful and laborious method of theoretical sampling, constant comparison and theoretical coding which underpins grounded theory research ensued in thirteen dimensions which were further advanced until theoretical saturation was established, the theoretical saturation resulted with emergence of the ten themes reinforced by constructs/concepts with associated allocated codes. The ten themes that emerged from the grounded theory research are adoption, shared vision, digital competitiveness, digital ecosystem, digital capability, digital investment, diverging interests, customer insights, digital culture, and operational efficiency. These emergent themes are the basis of the next leg of the research which is to develop a dynamic model archetypical of the digital embracing dynamics in the postal service in Southern Africa employing the System Dynamics modelling approach.

1. Introduction

The world is on the crossover to the digital era, which is transforming society and organizations across the world, an era also known as the Fourth Industrial Revolution. Digitalization is greatly plummeting the expenses of amassing, stockpiling, and administering data, thus altering commercial endeavours globally. Digital technologies provide opportunities to business, especially those in emerging economies, to take part international trade through e-commerce. This new digital revolution also known as the Fourth Industrial Revolution or its application in industry (Industry 4.0) requires alterations to current governance frameworks and has enormous repercussions for the Posts in the digital age [1].

In [2], the authors argue that Industry 4.0 can be well-defined as the innovative digital transformation for intuitive systems based on the astounding increase of the swiftness of information

managing, digital warehousing competence and immense advancement of information and communication technologies (ICT). The term "Industry 4.0" means the smart plants in which smart digitally enhanced devices remotely connected to enable communication of resources and materials through the business value-chain. This phenomenon is typified by responsiveness, proficiencies and efficiency [3].

Industry 4.0 is defined as a technology-based revolution, the emphasis being on autonomous systems with capacity and capability for quick information processing, big data storing capacity and capability and exponential increase in complex information and communication technologies (ICT) [2].

In [4], the authors postulates that Digital transformation (DT) can be characterized as an industry process developed to integrate digital technologies by synchronously streamlining business processes, goods, services, constructs, and company business models. Digital transformation originates from the collective

*Corresponding Author: Kgabo Mokgohloa, ajumar@buk.edu.ng

www.astesj.com

<https://dx.doi.org/10.25046/aj060236>

impacts of numerous digital innovations generated about novel players, structures, traditions, principles, and views that alter, jeopardize, replace or support prevailing guidelines of the way things are done within organizations, networks, businesses or turfs [5].

In [6], the authors advance that DT is understood as an assorted technology-based transformation in the firms that includes both the application of 21st era technologies to enhance standing processes and their efficiency, and the adventure into digital innovation, which possess the potential to transmute the business model of an organization. It has been demonstrated in the introductory section that the digital age and the ensuing transformative processes championed by the concept of DT are related with vigour, intricacy, and novelty and as a result a unique methodology is proposed to study the factors (barriers/inhibitors and drivers/enablers) associated with this phenomenon that continues to disrupt the world and shape the future.

This research paper adopted an inductive logic (theory building) approaches, this research will seek to comprehend critical inhibitors and enablers that play a role in technology and DT embracing in the postal service in the Region (Southern Africa) through analysis of secondary data from academic literature and industry reports. The theory building (inductive logic) will be conducted through Grounded Theory Research to solicit insights on the drivers and barriers of DT in the postal industry in Southern Africa.

In [7], the authors propose that Grounded theory (GT) has gradually surfaced as a renowned approach in social research for qualitatively investigating vibrant (dynamic) and unfamiliar phenomena. In [8] the authors reinforce this perspective and suggest that in the preceding two decades, an advance in curiosity in the field of grounded theory has been observed in the field of information system (IS). Digital transformation can be correlated to information systems which are a “component” of digital transformation relating to digitalization which must not be confused with digitization.

1.1. Problem statement

Conventional quantitative-based approaches are not able to fully delve into a phenomenon characterized by rapid change, dynamism, intricacy brought by multiple stakeholders with often conflicting interests and newness of the concept. The rigidity of traditional logico-deductive quantitative approaches makes it difficult to fully comprehend the era of the digital age and its bearing on the way postal services operate on the global arena and for the purposes of this research; the postal service in the Region (Southern Africa).

1.2. Research question

Can a conceptual framework be developed through a Grounded Theory research to explore the digital transformation adoption dynamics in organizations broadly and in the postal industry the Region (Southern Africa) in particular?

1.3. Closing notes to introduction section

The paper is divided into (a) Introduction which introduces the topic under study as well as clearly articulating the problem to be

resolved; and the research question which steered the research. (b) Literature appraisal section which delves into the GT research approach (c) Research methodology which articulates the philosophical worldview, the research approach (inductive approach), the research design (d) Discussion and findings which delves into the drivers and barriers of technology and digital transformation, and their transformation into emergent theory which is presented as findings; and (e) Conclusions and recommendations which provides deductions from the research and provides recommendations and expanses of forthcoming research.

2. Literature review

2.1. The Grounded Theory Research Method

In [9], the authors argue that whereas grounded theory did not altered in technique since conception in 1967, the aspect of GT's tenets has been expounded as the method advanced in practice. The processes of GT are intended to cultivate a cohesive basket of notions that provide a thorough theoretic elucidation of social phenomena under study. GT signifies an inductive examination in which the investigator queries data presented by respondents or taken from prior annals [10]; it (grounded theory) is a qualitative process of exploration in which investigators build hypothesis or theory from data at hand [11].

In [12], the authors advance that qualitative methods exhibit a dissimilar method to studious examination than techniques of quantitative research. Even Though the techniques are alike, qualitative methods depend on writings and image data, and have unique steps in data analysis, and pull from varied blueprints. Grounded theory is dissimilar to the dominant theory testing methods of investigation because, instead of beginning with a theory and systematically observing evidence to confirm the theory; grounded theory researchers on the other hand amass information and meticulously develop a mid-range purposeful theory grounded on that information amassed [11].

In [13], the authors elucidate that GT method entails a adaptable, yet distinctive, plans that differentiate it from other qualitative approaches, and it (GT) is chiefly relevant in greatly dynamic circumstances encompassing prompt and substantial change [10]. The unique characteristic of grounded theory is that it does not commence with a theory but instead extracts one from whatever emerges from an area of study [10]. This view is reinforced by [9] who propose that GT possess precise techniques for data gathering and assessment, while there is agility and leeway within boundaries; and GT scholar must understand these processes and related principles to be able to execute a study and these tenets are:

- (a) Data collection, and analysis are interrelated activities: In GT, the evaluation commences immediately when the preliminary set of data is gathered.
- (b) Notions (concepts) are the fundamental elements of analysis: A scholar operates with synthesis of data, not the with rudimentary data per se.
- (c) Groupings (categories) ought to be created and associated: Notions that correlate to the same fact may be assembled to form classifications (categories). Not all theories become groupings (categories). These categories ought to be elevated

in level and more conceptual than the notions (concepts) they express.

- (d) Selection (sampling) in GT progresses on theoretic grounds: Sampling in GT continues not in traction of extracting samples of specific clusters of people, time dimensions, but relates to notions (theories, concepts), their characteristics, extents, and differences.
- (e) Examination (assessment, analysis) employ a process of continuous contrasting: As a concept is observed, it is contrasted alongside further concepts for resemblances and disparities.
- (f) Archetypes and deviations must be taken into consideration: Information must be scrutinized for evenness (sameness) and for an appreciation of where that sameness is not evident.
- (g) Method (process) should be crystallized into theory: In GT, process (method) retains numerous implications. Process analysis could require decomposing a phenomenon into smaller chunks. Process may also denote resolute deed that may not be gradual, but changes in response to prevailing conditions.
- (h) Composing theoretic memos is an essential element to undertake GT research: Because the scholar may not easily keep track up with all the categories, attributes, propositions, and proliferation of questions that advanced from the investigative process, a systematic process to keep track of the evolution of the research should be in place. The usage of memos signifies such a system. Memos are not exclusively about "ideas", instead they are part of a meticulous research process in the construction and adjustment of theory.
- (i) Propositions (hypothesis) relating to associations among groupings (categories) should be established and substantiated during the research process: As suppositions (propositions) about linkages among categories are established, feedback mechanism to the field is a key requirement to ensure the dynamics are checked against material conditions in a dynamic setting and revised as required. A pertinent characteristic of GT is not that propositions remain unconfirmed, but that propositions are incessantly examined during the research process until they are confirmed or rejected.
- (j) A GT scholar should not work in isolation: A significant part of GT method is validating notions (concepts) and their causality with peers in similar research area.
- (k) Wider underlying circumstances must be explored and scrutinized however miniscule the research is: The assessment of a dynamic setting should not be constrained to the conditions that directly influence on the phenomenon of interest. Wider drivers influencing a phenomenon under study may include political, social, economic, cultural, technological, environmental, and other related factors.

In [14], the authors argue that in context of GT, data gathering commences without the creation of a premature hypothetical context (theoretical environment). Concepts (theory) is established from data produced by sequences of reflections. Information extracted from interaction of enablers and inhibitors in a dynamic setting is the building block towards the development of forecasts which are then verified in further observations that may confirm, or otherwise, the forecasts. "Grounded theoreticians have a common view with other qualitative scholars, that the traditional

tenets of "good science" should be preserved, but require recontextualization of the approach with a view to fit the certainties of qualitative research and the intricacies of social phenomena" [9].

In [11] the authors advance that GT is illusorily unsophisticated conceptually, yet meticulous and methodical in practice. Figure 1 depicts the method of GT which can be summarized as:

- (a) A scholar initiates data collection on a phenomenon of interest and explores the data by investigating patterns of occurrences to show concepts. Concepts are the key ingredient of GT, and conceptualization is one of its distinguishing characteristics.
- (b) The theoretical attributes of a category are established by assessing instances in incoming data with prior incidences in similar category. Throughout the evaluation process, the "core category" is established. The process of breeding categories and their characteristics proceeds up to the point where categories are "saturated"; that is, when additional collection of data does not yield any fresh characteristics to the present categories.
- (c) After saturation, the significant theory is contrasted to theories depicted in the literature.
- (d) Right through the process, the researcher transcribes memos capturing his or her reflections and logical procedures; the memos boost the emergent notions, classifications, and their interactions.

In [15], the authors cites [16] who theorises that grounded theory process is typified as a spiral that commences with collecting portions of data in a noteworthy expanse of enquiry which is coded and categorised in an ceaseless process that continues towards saturation and concludes in the theoretical compaction of concepts exemplified by a substantive theory. Figure 1 illustrates the grounded theory process as theorized in [11].

Figure 1: The Grounded Theory Method [11]

In [15], the authors further argue that while Figure 2 offers a high-level view of the process involved in grounded theory, it overlooks critical activities which include (a) Entering the field which encompasses (i) Problem explanation, and (ii) ensuring theoretical flexibility and relevance through a vigilant selection of

cases; (b) The part played by theoretical memos and extant literature in a GT study. The expanded Lehmann's research model proposed by [15] as depicted in Figure 3.

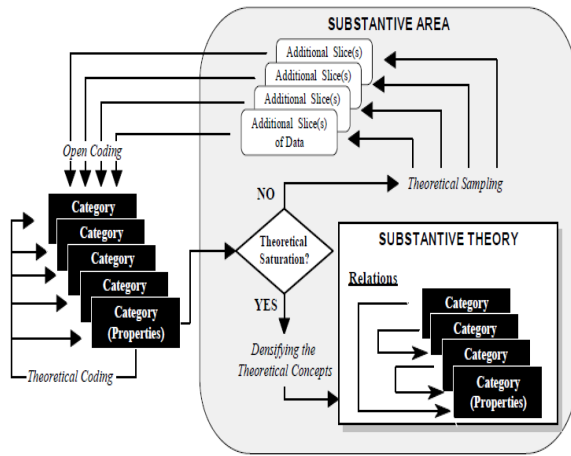

Figure 2: Lehmann's grounded theory process [15]

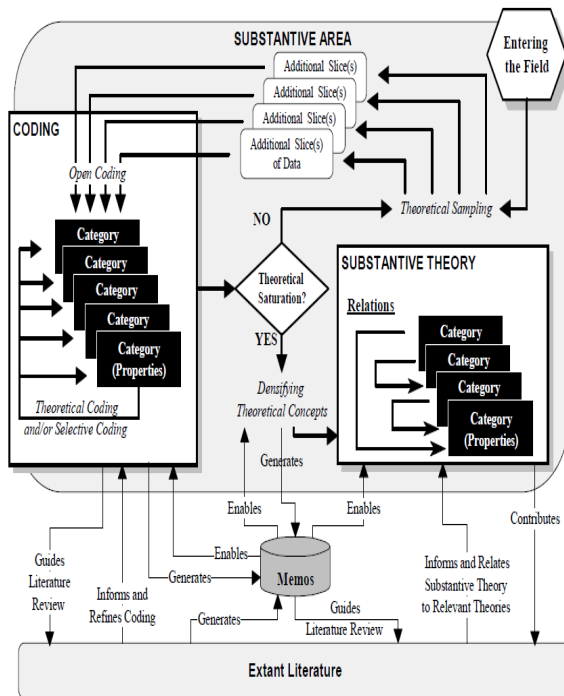

Figure 3: Expanded Lehmann's (2001) research model [15]

This research adopted a GT research method in the exploratory stage of the study through the interaction of the researcher with secondary data on technology and digital transformation adoption in organizations largely and cascaded down to the postal sector in the international context and regional (Southern Africa) context.

3. Methodology

In [17], the authors advance that research is a logical and methodical examination for applicable data on a specific topic of interest. This view is reinforced by [18] who contend that research is an organized process of gathering, examining, and deciphering data with a view of growing insight about a phenomenon under

study. In [19] the authors affirms the idea that research is an essential and compelling tool in guiding mankind towards progress. "Without logical research there would have been very little progress".

In [20] the authors proposes that another approach to research methodology development is constructed on the hypothetical concept of "research onion" proposed by [14]. The research onion delivers a comprehensive representation of the core tiers which are to be followed to devise an efficient and useful approach [21]. The research onion is depicted in Figure 4, it illustrates the layers from an all-inclusive philosophical viewpoint to the nuts and bolts of data collection and its respective analysis.

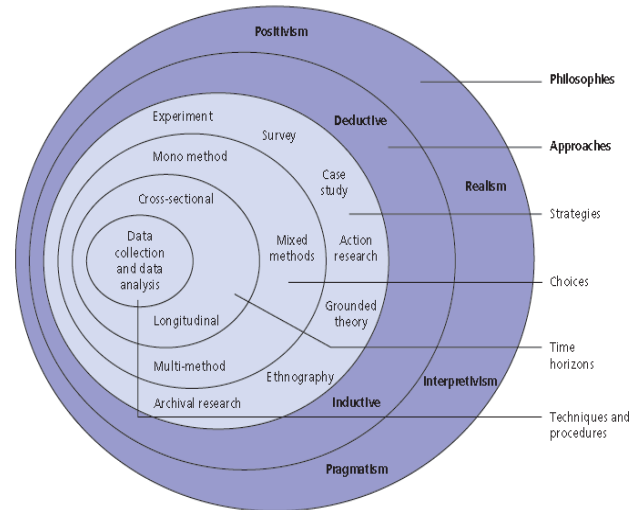

Figure 4: The research onion [14]

3.1. Philosophical worldview

In [22], the author suggests that the varieties of beliefs (philosophical worldview) held by individual researchers based on these factors will often results in the scholar adopting a qualitative, quantitative, or mixed methods approach in their research. This view is supported by [23] who maintains that the type of research approach the investigator adopts is informed by the viewpoint which the scholar holds to and the viewpoint will influence the research aim, the research tools designed and applied, as well as the pursuit for the resolution to the problem the scholar is exploring. These worldviews are post-positivism, constructivism, transformative, and pragmatism [12]. The major features of the four worldviews are outlined by [12] in Table 1.

The research philosophy adopted in this study reflects the way in which the researcher's worldview. The worldview and or viewpoint underpin the research methodology adopted.

Table 1: Major elements of the philosophical worldviews [12]

Positivism and Post-positivism	Constructivism/Interpretivism
Absolute	Insight
Reductionist	Multi perspectives
	Social and historical construction

Observed examination and dimensions.	Concept building
Concept testing	
Transformative	Pragmatism
Political	Arise from events.
Power and justice oriented	Problem-focused
Concerted	Diverse
Change-focused	Practical oriented

In [14], the authors argue that realism contends a key factor of the epistemology, ontology and axiology adopted by the scholar; is the research question. Ontology is focused on kind of realism and the crux of its being [17]; [14] which entails two ontological perspectives; objective reality and subjective reality [24]. Objectivism and subjectivism can be characterized as contrasting philosophical positions associated with the two perspectives [25]. Objectivism depicts the position that social entities occur in reality outside the social actors affected with their existence [14]; [25]. Subjectivism on the other hand asserts that social phenomena are inspired from the perceptions and subsequent acts of those social actors concerned with their existence [14].

In [14], the authors argue that epistemology is the study of the essence of knowledge and how it is developed, and offers a similar dualistic contest between positivism and interpretivism. Postpositivists hold a deterministic philosophy in which causes (most likely) determine effects or consequences [12], while interpretivism steadily hold that it is vital for the scholar to grasp discrepancies between people as social actors [14]. Views of the two poles are summarised in Table 2.

Table 2: Views of the two poles of research paradigm spectrum [24]

Paradigm	Scientific	Humanistic
Ontology	Objectivism	Subjectivism
Epistemology	Positivism	Interpretivism (Phenomenology)
Viewpoints	<ul style="list-style-type: none"> World is perceptible and precedes individuals. One reality The scholar is independent to phenomenon under study. Research focuses on reducing the problem to parts 	<ul style="list-style-type: none"> World is socially constructable. Multiple experiences The investigator is part of and interacts with phenomena under study. Research contextualizes phenomenon

3.2. Research approach

In [24], the authors propose that the progression of a new theory could be attained by commissioning two research approaches, deduction as depicted in Figure 5 (a) which can be defined as a step-down process towards theory testing or induction depicted in Figure 5 (b) which could best be defined as a step-up process towards theory building.

Figure 5: (a) Deduction approach: Adapted from [24]

Figure 5: (b) Induction approach: Adapted from [24]

In [24] the authors contend that deduction process involves an immensely structured technique and often dissects causal relations between elements in order to describe a specific phenomenon and engender a generalizable conclusions and often referred to as the 'top-down' approach; inductive theory-building on the other hand commences by definite detections in which outlines and relations are unearthed to develop concept (theory) about a specific phenomenon and could best be described 'bottom-up' approach. The key variances between deductive and inductive approaches to research are illuminated in Table 3, while Table 4 depicts the two research approaches and their consistent characteristics which provides a unified view of precepts of both deductive and inductive research approaches.

Table 3: Major differences between deductive and inductive approaches to research [24]

Deduction process	Induction process
Precise tenets.	Gaining insight
Shifting from notions/concepts to data.	Comprehension of research context

Causality needs to be explained	Assemblage of qualitative information
Resultant is quantitative information	Adaptable and shifts as research progresses
Controls to confirm authenticity of data.	Researcher not independent from research process
Concept operationalization for clarity	Generalization not an objective
Structured approach	
Researcher independent of phenomenon under research	Researcher part of the phenomenon under study

Table 4: Two main research approaches and corresponding attributes [24]

Research Approach	Deduction	Induction
Approach to inquiry	Extremely organized	Adaptable
Idea	Rationalist	Idealist
Sequence of inquiry	1. Concepts 2. Propositions 3. Examination 4. Validation	1. Examination 2. Insights 3. Propositions 4. Concepts
Purpose Data	Descriptive; Description of causal connections between variables	Probing; Gaining insights on phenomenon under study
Data Collected	Quantitative	Qualitative
Generalization	Necessity to generalize conclusions	No requirement to generalize conclusions

In [18], the authors advocate that a theory is an systematized form of concepts and principles envisioned to elucidate a specific phenomenon, and both deductive (positivist paradigm) and inductive (Interpretivist paradigm) approaches to theory testing and theory building respectively are similarly significant in engendering theoretical knowledge. They can together exist side by side [14], this view is supported by [24] who maintain that ontology cannot be detached from epistemology and reckons that “to talk of the construction of meaning is to talk about the construction of meaningful reality”, these two collectively inter-relate.

This research adopted the inductive logic (theory building) approach, this research seeks to grasp critical barriers and drivers that influence the digital transformation and technology adoption in the postal service in the Region of Southern Africa through analysis of secondary data from academic literature and industry reports.

3.3. Data collection methods and instruments

In [12] the authors argue that the goal of qualitative research is to resolutely choose participants or sites (or documents or visual material) that allows the scholars to grasp the problem at hand and to pose the appropriate research question that the study should seek to answer.

The data was gathered from secondary data from academic literature and industry reports, this data fixated on a array of aspects (drivers and barriers) widespread in adoption of technology and digital transformation in organizations broadly, but as well as in the postal industry. This exploratory aspect of the research was aimed at finding a resolution to the question “what are the technology and digital transformation adoption dynamics in organizations broadly and in the postal industry globally and in Southern Africa in particular?”

The research adopted the expanded Lehmann’s grounded theory research model method as proposed by [15] and as depicted in Figure 2. The study was further guided by the methodological steps depicted in Figure 3 to sift through data collected in the literature review to develop core categories. The grounded theory research originates by “entering” the field by posing a broad research question to guarantee divergent assemblage of data with no preceding ideas and paradigms in the broad sphere of technology and digital transformation adoption.

In [15] the authors advance that the initial phase of “entering the field” in GT research is meant to grasp and utilize continual contrasting. [8] endorses this view and propose that it is only through laborious evaluations (constant comparison) could a robust theory with one or more important classifications emerge as illustrated in Figure 6.

In [26] the authors argue that persistent contrasting method between proceedings (events) and settings (contexts) is the foundational power of grounded theory because through the four stages of the continual contrasting method which could best be articulated as (1) “Associating incidents applicable to each category”, (2) “Synthesizing categories and their properties”, (3) “Delineating the theory”, and (4) “Writing the theory”; the scholar relentlessly develop categories through the process of information assemblage, scrutinises and codes the data, and buttresses concept production through the process of theoretic sampling. [8] reinforces this view and emphasises that theoretical sampling is used to choose what to examine and it essentially concentrates on data collection.

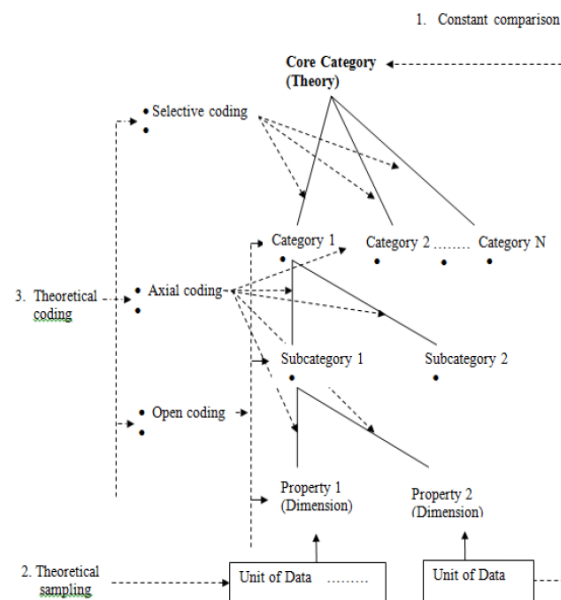

Figure 6: Grounded Theory method [8]

Figure 6 illustrates this phenomenon of the relations amongst the constant comparison method, theoretic sampling, and the theoretically sensitive coding which are the essence of GT research method.

4. Discussion and findings

4.1. Data analysis, coding, and results

Grounded Theory (GT) was adopted as a tool of analysis for the exploratory phase for this research because of its rigor in developing substantive theory.

In [27], the authors proposes that the three traits of grounded theory which are inductive, contextual, and operational fit with the interpretative nature of qualitative research. The process of analysis in grounded theory comprise of theoretical sampling, theoretical coding (comprising of open, axial, and selective); memo writing and theoretical coding [27]; while theoretical coding involves open coding, axial coding and theoretically sensitive coding [28]. Author in [15] suggests that theoretical saturation arises when additional sampling generates no further considerable value to the study and the theory becomes compressed (dense) with concepts, augmented by existing literature, and could then be deemed to be substantive theory. The endeavours involved in grounded theory methodology with regard to techniques and procedures of handling data are briefly explained below.

4.2. Theoretical sampling

In [29], the authors suggest that theoretical sampling is a vital principle of classic grounded theory, and is key to the progression and augmentation of a theory that is 'firmly grounded' in data, this view is supported by [30] who contend that "Theoretical sampling is a hallmark of grounded theory methodology". Theoretical sampling indicates additional data collection directed by the outcomes from previous data analysis. It seeks to assemble methodically additional data to explore emergent patterns. Significantly, at this stage, new data is used to validate, add to or query the emerging patterns as well as acknowledge gaps in the data analysis necessitating additional assessment or exploration [31].

In [32], the authors argue that theoretical sampling grows out of the process of breakthrough, reinforcing the approach which necessitates the scholar to take part in inductive as well as deductive reasoning. Inductive reasoning means shifting from examining occurrences or incidents, to forming a general abstract depiction with allusion to the specific attributes observed. Theoretical sampling can be viewed as a data triangulation method, it is utilized to create additional data to validate or rebut original categories until theoretical saturation is achieved [8], it serves as a thread that connects all dimensions of the grounded theory research process.

4.3. Theoretical memos

In [15], the author proposes that the composing theoretical memos commence instantaneously with open coding due to memos representing "the theorizing write-up of concepts about codes and their relations as they form in the mind of the investigator while coding". This view is captured by [9] who argue that memos evolve in complexity, compactness and exactness

during the unrelenting process of data collection to theorising, thereby boosting the theoretical fullness through ongoing process of comparison and conceptualization. Theoretical memos are an indispensable element to grounded theory research and it is incessantly performed during the data collection and analytical processes that embody the grounded theory research [8].

In [15], the authors argues that as richness and quality of codes and memos accrues, connections between them are perceived giving rise to a process called theoretical coding that gives rise to emergence of patterns and the start of sensitive coding. The goal of sensitive coding is to assimilate the diverse classifications established, expounded, and jointly related during axial coding into one robust theory [33]. Developing the emerging theory entails blending the classified memos and emerging theoretical outlines into a robust and comprehensible working theory.

4.4. Theoretically sensitive coding

Coding is an almost universal process in qualitative research; it is a fundamental characteristic of the analytical process and the ways in which scholars break down their data to create something new [34]. The author of [34] further proposes that coding is a way of indexing or mapping data, to provide an overview of distinct data that permits the scholar to grasp the data in relation to the research question posed.

In [27], the authors proposes that open coding is the investigative process upon which notions are recognized and their characteristics and aspects are unearthed in the data. Axial coding on the other hand includes synthesizing data (splintered through open coding) in new-found data by forming interactions between categories and their subcategories; Axial codes normally denote categories that describe the open codes [27] and [9] points that axial coding is required to probe the relationships between conceptions and classifications that have been developed in the open coding process which according to [15] entails exploring data to unearth a set of classifications and their attributes. [8] proposes that axial coding is a set of techniques to establish causality among categories and subcategories by synthesizing information and crystalizing it in a new way following open coding process.

In [27], the authors advance that selective coding is aimed at integrating and enhancing the groupings into a notions, which accounts for the event being explored and reinforces the statements of relations among concepts and fills in any categories in need of additional enhancement. In this analysis data analysis immediately trailed data collection. Constant comparison process is (data assemblage and data evaluation) achieved when no further information that is significant is unearthed suggesting that theoretical saturation has been attained.

4.5. Discussions

Emerging categories evolved from the grounded theory process that was articulated earlier in this study. A wide range of source documents were reviewed which explored topics such as Innovation Diffusion Theory (IDT), Theory of Reasonable Action (TRA), Technology Acceptance Model (TAM), Technology Acceptance Model 2 (TAM2), Unified Theory of Acceptance and Use of Technology (UTAUT), ADOPT Framework all led to an emerging dimension that could better be described as Individual Drivers.

The second emerging category that could better be described as Organizational Drivers, emerged from review of factors associated with Benefits, Organization and Technology (BOE), Technology, Organization and Environment (TOE), Innovation Capability Model (ICM), Digital Framework, Digital Capability Framework, and Driving process of Industry 4.0.

The third emerging category that can be condensed as Organizational Barriers emerged from literature relating to barriers of Industry 4.0 and technical barriers to Information & Communications Technologies (ICT). The fourth emerging category was Technological Drivers which emerged from review of literature with topics relating to digital maturity framework, industry 4.0 design principles and technology organization environment (TOE) model. This fourth category is balanced by a fifth category that emerged which is an inverse of the fourth category which could be summated as Technological Barriers which emerged from review of articles relating to barriers of Industry 4.0 and technical ICT barriers.

Other categories that emerged was the sixth category which was Environmental Factors (Internal) that emerged from review of literature relating to drivers to digital embracing in the postal industry, the seventh category that emerged was Environmental Factors (External) that emerged from review of literature relating to barriers to digital embracing in the postal industry. The seven dimensions are depicted in Table 5.

Table 5: Emerging categories and concepts/constructs/variables [Authors elaboration]

Emergent Categories	Variables and codes
Individual drivers	Relative advantage (A), Compatibility (B), Complexity (C), Trialability (D),
	Attitude towards the behaviour (E), Subjective Norms (F), Intention towards behaviour (G)
	Perceived Usefulness (H), Perceived Ease of Use (I), Attitude Towards Uses (J), Behavioural Intention (K), Actual System Use (L)
	Subjective Norms (M), Voluntariness (N), Image (O), Output Quality (P), Job Relevance (Q), Results Demonstrability (R), Perceived Usefulness (H), Perceived Ease of Use (I), Intention to Use (S), Usage Behaviour (T)
	Expectancy performance (U), Effort Expectancy (V) Social influence (W), Facilitating Conditions (X), Gender (Y), Age (Z), Experience (AA), Voluntariness of Use (AB), Intention to Use (AC), Use Behaviour (T)
	Innovation characteristics (AD), Population characteristics (AE), The actual relative advantage of using the innovation (AF), Learning of the actual relative advantage (AG)
Organizational drivers	Professed Benefits (AH), Organizational readiness (AI), Regulations (AK), Competition (AL)
	Industry attributes & market composition (AM), Technology infrastructure (AN), Government regulation (AK), Official and unofficial structures (AO), Communication processes (AP), Organizational magnitude (AQ)
	Optimize the competence base (AS), Business intelligence (AT), Inventiveness and idea

	management (AU), Organizational structures (AO) and systems (AV), Culture and climate (AW), Management of technology (AX), Innovation new stream (AY), Innovation mainstream (AZ), Innovation capability (BA), Innovation performance (BB),
	Strategies (AR), Customer relationships (BE), Business models (BF), Corporate structures (AO), and inter-organizational processes (BG) Customer & product knowledge (BH), Defined responsibilities (BI), Collaborative organization with flat hierarchy (BK), Empowering leadership (BL)
	Marketplace competition (AL), Market trends (AL), Competition pressure (AL), Business innovation model (BM)
	Value creation (BN), Business Processes (BO), Training (BP), Change Management (BQ), Culture-Leadership-Values (AW), Innovation Capability (AU-AY-AZ-BB), Transformation Capability (BR), Customer Centricity (BS), Operational Excellence (BT)
	Reduce mistakes (BU), Improve lead times (BV), Improve competence (BW), Improve operational efficiencies (BX)
	Vertical integration (ET), Horizontal integration (EU), Innovation push (BB)
	Deviant logic (FB), Discovery (FC), Development (FD), Diffusion (FE), Impact (FD), Adoption (FE)
	Digital maturity (FF), Digital readiness (FG), 2IPD (FH), Firm performance (BC)
Emergent categories	Variables (concepts) and codes
Organizational barriers	Weak organizational structure and process (AO), Contradictory interests (BY), Employee and middle management resistance (BZ), Lack of upfront planning(CA), Lack of vision and strategy (AR), Poor digital savvy culture and vision (BJ), Organizational readiness (Inhibitors) (AJ)
Technological drivers	Technology Availability (CB), Technology Characteristics (CC), IT excellence (CJ), Interoperability (CD), Virtualization (CE), Decentralization (CF), Real-time capability (CG), Service Orientation (CH), Modularity (CI)
Technological barriers	Poor communications protocols (CK), Poor system integration (CL), Poor supply chain integration (CM), Lack of standards ((CN), Lack of common vision (CP), data security weaknesses (CQ), Storage capacity (CR)
Environmental factors (Internal)	Staff (CZ), Financial capacity (DA) Process improvement (ER), Workplace improvement (ES), Cost reduction (EW) Employee support (EZ) Digital innovation (FA) Management support (EV), Customer demands (EX), Resource constraints (DE), Poor transition towards digital culture (DF), Limitations of IT infrastructure (DG) Lack of sufficient internal expertise required to develop e-services (DH), Custom clearance (DI), Meagre digital culture (DJ), Corruption (DL), Unnecessary red tape (DN), Micromanaging (DT), Lack of cultural knowledge (DU), Resistance to change (DV), Fear of technology (DW), Lack of relevant local content (DX), Lack of maintenance culture (DY), Lack of language skills (DZ), Low income (EA), Lack of investment (EB), Low

	return on investment (EC), High initial costs (ED), High risk on investments (EE)
Environmental factors (External)	Legal and regulatory framework (AK) Public trust (DC), National policy alignment (DD), Political commitment (DB) Network (Spectrum) (CY), Supply chain transformation (EY) Market pressure (AL), Laws & regulatory framework (AK) Slow customer adoption of digital services (DK) Corruption (DL), Lack of political will (DM), High taxes (DO) Lack of regional initiatives (DP), Political instability (DQ), Lack of proper planning or coordination (CA), Monopoly (DR), Invisible hand (DS), Perceived lack of privacy (EF), Insecurity (EG), Lack of proper legal framework (AK), Poor regulation (AK) Lack of software and hardware (EH), Inadequate of electricity supply (EI), Lack of internet exchange points (EJ), Scarcity of technical personnel (DH), High illiteracy rates (EK), Lack of ICT skills (DH), Lack of Research & Development outputs (EL), Increasing labor shortages (EM), Reducing monotonous tasks (EN), Work force realignment (EO), Lack of 21 st century skills (EP), Lengthier learning times (EQ)

4.6. Critical Findings

The seven categories that emerged were further synthesized into ten emerging themes which are (a) Adoption (b) Shared vision (c) Diverging interests (d) Digital competitiveness (e) Customer insights (f) Digital ecosystem (g) Digital capabilities (h) Digital investment (i) Operational efficiency, and (j) Digital culture. These ten emerging themes are depicted in Table 6.

Table 6: Emerging final themes and associated categories [Authors elaboration]

Emergent Themes	Coded variables (concepts)
Adoption	A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, S, S, T, U, V, W, X, Y, Z, AA, AB, AC, AD, AE, AF, AG.
Shared Vision	AR, BI, BK, AH, AO, AP, BF, AO, BL, BQ, BR, CA, AR, CK, CN, EZ, EV, DH, DX, DC, DD, DB.
Diverging Interests	BY, BZ, CM, CP, DL, DN, DT, DV, DQ, DS.
Digital Competitiveness	AT, BN, BO, FD, FH, BC, CG, FA.
Customer Insights	BE, BH, BS, EX.
Digital Ecosystem (UPU standards and systems)	AM, AI, AL, AK, DK, DP, DR.
Digital Capabilities	AN, BA, BM, AU, AY, AZ, BB, ET, BB, FE, FF, CB, CC, CJ, CD, CE, CF, CG, CQ, DG, DI, CY, EF, EG, EH, EJ, DH, EL, EN.
Digital Investment	AI, DA, DE, EA, EB, EC, ED, EE, DK, EM.
Operational efficiency	AX, AY, AZ, AQ, AS, BG, BP, BT, BU, BV, BW, BX, CG, CL, CQ, CZ, ER, ES, EW, CA, EH, DH, EO, EP,
Digital Culture	AW, FD, FB, FC, FE, FG, BJ, AJ, DF, DJ, DU, DW, DY, DZ, EQ.

4.7. Conceptual framework

Theory is a vast notion that arranges many other notions with a high intensity of descriptive (explanatory) power. Theory of method offers direction to make sense of what methods will essentially assist in responding to the research questions posed in a particular study [35]. Theories prudently define the exact descriptions in a specific realm to clarify why and how the relations are rationally tied so that the theory provides predictions. Consequently, the exactness of good theory triggers a theory to be very accurate for all the vital elements of a theory [36].

A theoretical framework is an edifice that abridges notions and theories developed from earlier verified and available knowledge synthesized to develop a theoretical background, or source of data evaluation and interpretation of the meaning contained in the research data [37]; it therefore infers that a theoretical framework aids as the basis upon which a research is constructed [38]. A theoretical framework denotes to the theory that is adopted by the researcher to guide the research path; as a result a theoretical framework can be defined as implementation of a particular theory, or established concepts drawn from related theory, to provide an elucidation of an event, or provide in-depth insight on a specific spectacle (phenomenon) or research problem that requires resolution [39].

An abstract (conceptual) framework on the other hand is an edifice which the researcher considers to best enlighten the organic advancement of the phenomenon under study [37]. On the other hand, a researcher may believe the complexity of the research problem under study cannot eloquently be explored with focus on only one concept, or concepts engrained within a single (integrated) robust theory; and this triggers the researcher to “synthesize” the current views expressed in literature in the form of theoretical and from empirical findings relating to area under study. The fusion (synthesis) could best be described as a conceptual framework, which in essence embodies an ‘integrated’ vision of the problem under study [39].

A conceptual rather than theoretical framework approach was adopted as the grounded theory approach presented in 2.1 and the elucidation presented in 4.5 encompasses multiple dimensional theories and concepts as presented in Table 5, which are synthesized to develop final themes as presented in Table 6.

The proposed conceptual framework presented in Figure 7 denotes illumination of the insights and subsequent synthesis of the grounded theory research which was elaborated upon in previous sections of this paper. The Universal Postal Union (UPU) endeavours to create a digital ecosystem through its business processes, standards, and systems which the postal sector transacts in, the digital ecosystem facilitates a shared vision which is depended on customer insights which leverage the shared vision and improves the digital ecosystem.

Adoption of the systems, standards, and protocols of the UPU entrenches a deep and robust digital culture. A robust digital culture on the other hand enhances the digital ecosystem and enables a shared vision. A clear and unambiguous shared vision amongst stakeholders drives operational efficiencies and triggers digital investment. Digital investment develops digital capabilities and on the other hand operational excellence enhances digital

capabilities. Digital capabilities ensure digital competitiveness which incorporates factors such as digital innovation and digital disruption.

Diverging interests which denotes barriers ranging from institutional to organizational inhibits or rather curtails a shared vision and ultimately negatively affects the path towards digital competitiveness. Customer insights, digital ecosystem and digital culture are inputs to a shared vision which ensures the development of digital capability through operational excellence and digital investment which results in digital competitiveness. It is crucial to mitigate diverging interests in order to achieve digital competitiveness which guarantees sustainability of the postal sector.

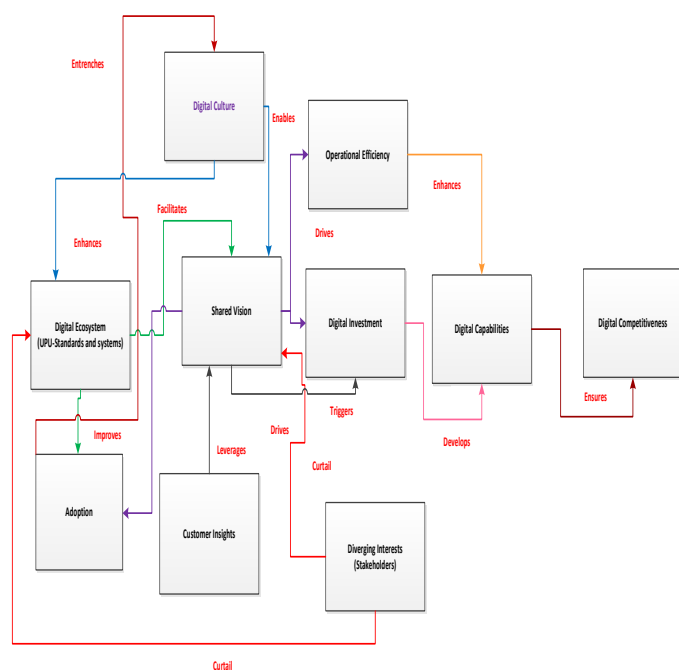

Figure 7: Conceptual framework [Authors elaboration]

4.8. Conclusion and future research

The world is faced with sweeping revolutionary changes ushered by the digital age, which is altering the world as we know it. The postal industry is not operating as an island and therefore not detached from this new phenomenon of the digital age which is blowing strong winds of change whose strong currents are disrupting all sectors of society on a global scale. Business models are being disturbed across all industries including the postal service.

The phenomenon of digital transformation was introduced, followed by an in-depth review of literature on Grounded Theory (GT). The GT process was presented as well as the research methodology adopted in this study which articulated the "research onion" which delved into research philosophy, research approaches and the research design which comprised of research strategy, research choice, time horizons, and data collection & analysis techniques and procedures.

The data analysis coding and results were presented in which theoretical sampling, theoretical memos, and theoretically sensitive coding were highlighted. The initial thirteen emerging

categories were presented and discussed. The 13 initial emerging categories were further synthesized upon which nine key themes emerged which were presented. A conceptual framework that elucidates the nine themes was presented and explained.

The gap acknowledged in this study is the difficulty of traditional logico-deductive approaches to explore phenomenon characterized by newness and extreme dynamism such as disruptive technology, digital transformation which is buttressed by a diversity of enablers and inhibitors that range from technical barriers and drivers to soft issues such as digital culture for instance. It is said that culture can eat strategy for lunch, which means that should the culture of an organization not be matured and developed; no amount of strategizing and deployment of technologies will see the light of the day.

As a recommendation towards future research, the ten emerging themes and their associated categories and constructs of the categories will be utilized in the development of a unified conceptual framework through application of System Dynamics as a modelling tool. Anylogic software will be used as the preferred modelling software to model the dynamics associated with digital transformation and technology adoption of the postal sector in Southern Africa. It is envisaged that modelling the nine emerging themes in a dynamic setting will provide insights and patterns that emerge from causality and feedbacks as factors (barriers and drivers) interact.

Conflict of Interest

The authors declare no conflict of interest.

Distribution network

ABSTRACT

Integration of Distributed Generation (DG) on distribution networks has a positive impact which includes the following: low power losses, improved utility system reliability and voltage improvement at buses. A real distribution network is radial in which energy flow is unidirectional from generation to transmission and from distribution to the load. However, when a DG is connected to it, the power flow becomes bidirectional, and the protection setting of the network may be affected. Therefore, the aim of this research work is to investigate the impact of distributed generation DG on power system protection. The test distribution network is first subjected to load flow analysis to determine its healthiness with and without DG connection. The load flow results confirm that the integration of the DG into the distribution network reduces the active power load loss by 92.68% and improves voltage profiles at each bus of the network by 90.72%. Thereafter, the impact of DG on the protection setting of the existing test network was investigated. Integrating DGs to the network, from our result, shows an increase in the fault currents, which in turn caused false tripping, nuisance tripping, and blinding of protection relay compared with when DGs are not connected. The protection relays were reset at the point of common coupling (PCC) to prevent any abnormal tripping. This is the major contribution of the research work.

1. Introduction

Integration of distributed generation (DG) into the distribution systems offers many advantages and disadvantages to the distribution network [1, 2]. Economic and environmental benefits, and increased penetration of DGs, will impose significant technical barriers on the efficient and effective operation of the distribution systems. Increase in fault current and changes of power flow from unidirectional to bi-directional are the major two impacts of DG on the distribution networks, and these affect the existing protection of the distribution system relay, especially the over-current relays. Therefore, the impacts of DGs on the existing distribution system must be thoroughly investigated in order to ensure the stability and reliability of the system. The integration of DG into the distribution network has a great impact on the steady-state and transient behaviour of the network which depends on the DG capacity and penetration levels, type of generator, the method

by which the generator is interfaced with the network and the location of the connected DG [3, 4], just as in the case of capacitor and or phase measurement unit (PMU) placement. The steady-state behaviour of the network describes the healthiness of distribution network before and after the integration of the DG. This is carried out by load flow analysis on the network, while the transient behaviour of the network has to do with the stability and the setting of the protection relay [3] which is a major concern in this research work. Among all other challenges affecting the integration of DG into the distribution networks, protection issues are considered one of the major concerns because they are directly related to the system's safety and reliability.

DG has positive and negative impacts on the distribution networks. DG positive impacts are as follows, improved the voltage profile, improved power quality, and reduces the power losses in the distribution network; it eliminates the additional transmission and distribution capacity and improved reliability of the system [5, 6] among others. The negative impacts include lack

*Corresponding Author: Tobiloba Somefun, Email: tobi.shomefun@covenantuniversity.edu.ng

of safety of the public and utility personnel, damage to the plant in the event of unsynchronized reclosure protection performance degradation, etc. [7, 8]. The integration of DGs makes the distribution network no longer operate as a passive system but now operates as bidirectional power flow which may affect the network protection. This could lead to lack of relay coordination among the different protection schemes of the system [9, 10]. Therefore, the traditional protection schemes used in the distribution system need to be re-evaluated or reset with the integration of DG. However, before the protection issues are considered, it is very necessary to ascertain the healthiness of the existing distribution network with and without DG connection. Emphasizes here are on the power losses and voltage profile at each bus.

2. Literature Review

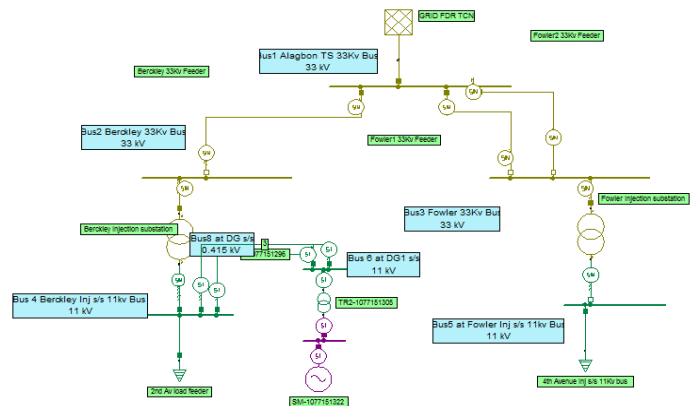

This section provides a critical review of the relevant literature that is related to the study. The impact of DG on short circuit current flowing in the network depends on the location, capacity and the type of bus to which the DG is connected. Utilities are no longer embarking on building large generating plants. Distributed generator serves as an alternative for generating energy resources [11]. There are many benefits of DG integration, but the penetration of DG into the distribution network may cause protection issues in the existing distribution network because it is designed to operate as a radial network. The major challenges that are related to power system protection as a result of the integration of DGs according to reference [12] include the following: blinding, false tripping of feeders, nuisance tripping of protection schemes, unintentional islanding, increasing of fault levels, neutral shifting, resonance, automatic recloser out of synchronism.

False tripping and islanding operations were prevented via proper coordination of the protection relay with high penetration of DG into the distribution network according to the investigation by authors in references [9,13]. Also, [14] researched the effect of protection and fault current on high penetration of DG with the distribution system. His result showed that the penetration of DG in the distribution increased the fault current in the system. Author [15] also worked on the DG imposed technical barriers for effective and efficient operation on distribution network with fast reclosure, his result revealed that fault current increased with the capacity and penetration level of the DG connected to the distribution network. Authors in [16] also investigated the relay protection coordination in the presence of high penetration of DG with the distribution system, and he concluded that the penetration of DG affects the protection of the existing distribution network which required resetting of the protection relays. Authors in reference [17] worked on reducing the fault current and improving the quality of power system reliability with Solid State Fault Limiter (SSFL) to replace substation equipment he concluded that the protection system of DG with SSFL is preferable to compare to without SSFL. Author in reference [18] analyzed the relay coordination challenges in the presence of DG with different types of DGs and its capacity using Fault Current Limiter FCL series reactance, and he concluded that the fault current on synchronous generators (SG) is more pronounced compared with other DG such as doubly-fed Induction Generator (DFIG). He stated that the protection relay coordination's integrity could be more preserved using series reactance fault current limiter.

In this research work, the load flow analysis of the test distribution network is first analyzed using Neplan software to confirm the distribution network's healthiness before and after the integration of DG. This is because an unhealthy distribution network will be much more affected negatively with DG integration. Many of the authors above failed to do this. Also, a real distribution network is used for this investigation and not test distribution network. The DG penetration level into the distribution network is analyzed and with the relay tripping time. The maximum DG penetration level in each bus that will not give rise to protection miscoordination is analyzed.

3. Materials and Methods

The distribution system is modelled using Neplan software. The grid components parameters are collected from Eko Electricity Distribution Company which include the transmission line, number of buses, transformers and load information. The essence of load flow study is to investigate the voltage profile on each bus, the real and reactive power load loss in the network. The load flow analysis was designed to assess the steady-state performance of the distribution network under no-fault conditions. The load flow analysis was carried out on the distribution network with or without distributed generation connected to it. The distribution network was modelled for protection relay coordination with Neplan software. Simulation of the entire distribution system was done to investigate the effect of the penetration level of DG on distribution system protection. The single line diagram of the modelled distribution network is as shown in Figure 1.

22MW is connected to bus4 by 11kV double line circuit via bus6 with a power transformer and 0.415kV bus8. Fowler 1&2, 33kV line double circuit feeds Fowler 15MVA Injection substation via 33kV bus3, the primary side of the power transformer is connected to bus3 while the secondary side is connected to 11kV load bus5 with 9MW load. Interconnector line is connected to the bus2 and bus3 for flexibility of the network. The line impedance of the distribution network used for this research is $R = 0.101$ and $X = j0.077$, data collected from the utility company. From this, it can be seen that R/X Ratio is 1.311688, which is high compare to the transmission network, which is always less than 1. Also the conventional load flow analysis will not converge for the distribution network because of the high R/X Ratio [19]. Hence NEPLAN software is used to carry out the load flow analysis of this study.

3.2. Results of Load-flow on the test distribution network

The result of power loss with and without DG attached to 11Kv bus in Berkeley injection substation is shown in Table 1 while Table2shows the voltage profile of the system with and without DG connected to the distribution network. Figure 2 gives the graphical representation of voltage profile with and without DG.

Table 1: Result of power loss without and with DG

S/N	Substation Load (MW)	Active Power load loss (Mw)	Reactive Power load loss (Mvar)	Status
1	8.3	0.123	1.111	without DG
2	8.3	0.009	0.007	with DG

Figure 2: graphical representation of the voltage profile of with or without DG

Table 2: The voltage profile of the system with and without DG

S/ N	BUS	Nominal voltage (Kv)	Bus voltage (Kv)	Per Unit (p.u)	Status
1	4	11	10.269	0.934	without DG
2	2	33	32.922	0.998	
3	7	33	32.999	0.999

5	6	11	10.988	0.999	
6	8	0.415	0.415	1	

4. DG Penetration at Berkeley (buses 4,6&8) Injection Substations

The effect of distributed generation can be analyzed by connecting the generators to the load buses one after the other and confirming their simultaneous effect on the system [20]. Traditionally the power flow in the distribution system is unidirectional without distributed generation, but the integration of Distributed Generation makes the energy flow bi-directional, causing loss of relay coordination in the systems. The technical challenges between DG and protection schemes are the increase in short circuit fault currents, lack of relay coordination in the protection system, failure to the closure of line after the occurrence of a fault in the networks, effect of islanding and untimely tripping of DG interface on the protection systems of the distribution systems.

The impact of penetration level of the DG on the distribution network cause protection miscoordination which can be analyzed as follows, the Distributed Generation Penetration Factor (DPF) and is plotted against the Protection Mis-coordination Index (PMI) [21].

$$DPF = \frac{DG_{connected\ to\ Bus} \text{ (MW)}}{SystemLoad \text{ (MW)}} \quad (1)$$

$$PMI = \frac{Miscoordination \text{ events}}{Total \text{ Fault events}} \quad (2)$$

5. Results and Discussion

5.1. Simulation by Penetration of DG at bus 4 of Berkeley Injection Substation

Figures 3 and 4 show the single line diagram of three-phase fault simulated without and with DGs connected respectively. The penetration level of DGs into the test distribution network is done by simulation of three-phase fault using Neplan software to confirm the level at which the penetration of DGs affects the distribution network's protection system. Table 3 shows the simulation result of fault current and time of tripping without DGs connected. Also, it can be observed from the result of the simulation in Table 4 that as the capacity of the penetration level of DGs increases, the fault current likewise increases while the tripping time of the relay protection decreases. This is to confirm that the integration of DG into the distribution network causes an increase of the fault current in the distribution network, compare with what is seen in Table 3 when DG is not connected.

Table 3: The simulation result of fault current and time of tripping without DGs connected

Bus	Fault Current (IKA)	Time (s)
1	0.962	1.66
2	0.962	0.259

Blinding and false tripping

Figure 5 shows the plotting of DG penetration (MW) against the protection miscoordination time (PMT) and corresponding fault current (kA) of the integration of DG into the test distribution network.

The DG penetration level cause protection first miscoordination to beginning at 0.595MW and 0.765MW, the second miscoordination occur at 2.805MW, and 2.975MW and third miscoordination occur at 9.945MW and 10.115MW on 11kV line with system load of 8.3MW, therefore, false tripping, nuisance tripping and blinding of protection occur when the penetration of DGs get to the point of fault at the external of the protection zone, that is when the DGs penetration level increases fault current beyond the protection relay setting as seen in Table 4.

Figure 5: Graphical representation of DG penetration

Recalling equations 1&2

The first miscoordination,

$$DPF = \frac{0.595}{8.3} = 7.1\%$$

$$\text{and } DPF = \frac{0.765}{8.3} = 9.2\%$$

The second miscoordination,

$$DPF = \frac{2.805}{8.3} = 33.8\%$$

and

$$DPF = \frac{2.975}{8.3} = 35.8\%,$$

The third miscoordination,

$$DPF = \frac{9.945}{8.3} = 119.8\%$$

$$\text{and } DPF = \frac{10.115}{8.3} = 121.8\%$$

$$\text{Then, } PMI = \frac{6}{1} = 6$$

$$DPF = (0.595)/(8.3) = 7.1\%$$

and

$$DPF = (0.765)/(8.3) = 9.2\%$$

The second miscoordination,

$$DPF = (2.805)/(8.3) = 33.8\%$$

and

$$DPF = (2.975)/(8.3) = 35.8\%,$$

The third miscoordination,

$$DPF = (9.945)/(8.3) = 119.8\% \text{ and}$$

$$DPF = (10.115)/(8.3) = 121.8\%$$

$$\text{Then, } PMI = 6/1 = 6$$

The calculation shows that the first blinding of protection of the system beginning at the penetration level of 7.1% and 9.2% of DG, and the second false tripping of the protection start when the penetration of the DG gets to 33.8% and 35.8% while the third false tripping protection begins at maximum penetration of DG at 119.8% and 121.8% with the system load of 8.3MW and this is the best penetration level because the DG is able to accommodate

the system load of the injection substation without any further tripping after reset the protection relay..

Also, PMI shows the time of occurrence of miscoordination which is 6 times, that is, the protection miscoordination time at first miscoordination is 6.984s and 32.572s, the second miscoordination is 1.891s twice, and the third miscoordination is 1.664s twice as seen in Table 4.

From Table 1, the result of load flow analysis on the test distribution network using Neplan software shows that the active power load loss without DGs is 0.123MW compare with 0.009MW when DGs is connected to the system. It can be established that the active power load loss is very high without DGs connected to the system compared to when it is connected. This shows that the DGs connected to the distribution network improves the active and reactive power, as seen in Table 1.

From Table 2, the result of the load flow analysis shows that the voltage profiles at buses 4, 2 and 7 are 0.934p.u, 0.998p.u and 0.999p.u without DGs connected are compared with voltage profiles at buses 4, 6 and 8 are 0.999p.u, 0.999p.u and 1p.u when DGs connected to the system. The result confirmed that the voltage at each bus improved when DGs connected to the test distribution system. From the load flow analysis results, it can be concluded that the test distribution network is healthy enough to accommodate DGs.

From Table 4, as the penetration of DGs increases from 0.595MW to 0.765MW and from 0.935MW to 1.105MW, the fault currents increase likewise from 7.227KA to 8.839KA and from 10.214KA to 11.369KA respectively at first miscoordination, however the time to which the circuit breaker opens the fault fluctuates from 6.984s to 32.572s and from 6.789s to 4.288s respectively. This is abnormal because the time at which the breaker isolates the fault should not under any condition rise from 6.984s to 32.572s and later decrease to 6.789s, so this calls for protection resetting to prevent the blinding, false, and nuisance tripping that has already occurred.

The second miscoordination occurred as the penetration level is increased from 2.805MW to 2.875MW, thereby causing the fault current also to increase from 16.226KA to 16.4KA. However, the time to which the breaker isolates the fault is constant at 1.891s. This is also abnormal because the time at which the breaker opens the fault should be less than 1.891s. So, this calls for relay resetting to prevent the blinding that has already occurred.

The third miscoordination occurred as the penetration level is increased from 9.945MW to 10.115MW, thereby causing the fault current also to increase from 17.871KA to 17.876KA. Moreover, the time to which the breaker opens the fault is constant at 1.664s. This is abnormal because the time at which the breaker isolates the fault should be less than 1.664s. So this calls for relay resetting to prevent the blinding that has already occurred.

The simulation result confirms that the integration of DGs into the existing test distribution network as shown in Tables 4 causes an increase in the fault current which in turn caused false tripping, nuisance tripping and blinding of protection relay compare with when DGs not connected as shown in Table 3. At this point, the settings of the protection relay at the point of

common coupling (PCC) of DGs to the test distribution network is important to prevent false tripping, nuisance tripping and blinding of the protection relay because of the flow of electricity that change from unidirectional to bi-directional flow.

6. Conclusion

A single line diagram was developed for the test network, and the impact of Distributed Generation (DG) on power system protection was also investigated in this study. It can be concluded that as the capacity of the penetration level of DGs increases, the fault current likewise increases while the tripping time of the relay protection decreases. This confirms that the integration of DG into the distribution network causes an increase in the fault current in the distribution network which in turn will affect the protection setting. For instance, integration of DGs at 11kV line, in this work, causes the miscoordination of protection relay to occur first at the penetration level of 7.1% and 9.2%, second at 33.8% and 35.8%. At the same time, the third false tripping protection begins at the maximum penetration level of the DGs at 119.8% and 121.8%. Blinding, false and nuisance tripping happened at 32.572s, 1.891s and 1.664s respectively. The protection relays at the point of common coupling within the test distribution network were reconfigured to prevent such occurrence again. This was done by calculating the following: Relay current at fault location, Plug setting multiplier, Pick-up current and the Operating time.

Conflict of Interest

The authors declare no conflict of interest.

Information System

ABSTRACT

The advancement of artificial intelligence is quick as it can be quickly deployed in many ways, such as medical diagnosis. Lung cancer is both men's and women's deadliest form of cancer. The best clinical approach to non-small resectable cell lung cancer treatment is surgical. Patients who undergo lung cancer thoracic surgery do so with the hope that their lives will be prolonged for a reasonable period afterward. In this paper, we suggest an expert system for calculating the risk factor for mortality one year after thoracic lung cancer surgery. Centered on clinical and functional evidence from cancer patients with lung cancer resections, we are developing an interesting hybrid model combining near sets with soft sets, namely soft near sets. as a system for not only predicting patient lung survival or not but also, to determine the degree of risk. Some fundamental concepts of the proposed model are introduced. Basic properties are deduced and supported with proven propositions. The correct survival classification is done with 90.0 % accuracy. Our innovative soft-near set-based criteria for determining the survival rate is an effective and reliable diagnostic process. Identify the possibility of lung cancer surgery will help the doctor and patients make a more informed decision about how to locate the treatment methods.

1. Introduction

More recently, scientists have been interested in ambiguity modeling so that they can describe and extract useful information hidden in uncertain data [1]. In 1999 [2] the author introduced a new mathematical method to overcome uncertainties. It is referred to as a soft set that has rich application potential in many directions. In [3] the author present the implementation of soft set theory in a decision-making dilemma, and extended to fuzzy soft sets by classical soft sets in [4]. Established interval-valued fuzzy soft sets by author in [5]. In [6] the author also presented a new concept of soft set parametrization reduction. Several researchers have recently investigated the application of hybrid soft-set models in different systems, such as [7–10].

In [11], the author initiated the perception of rough set theory. A set is considered rough if the boundary between its lower and upper approximation is nonempty. Near set theory, proposed by author in [12], Differ in terms of the boundary principle of the set

approximation by traditional rough set. In [13–15], the authors studied it in many papers.

Near set theory provides a description-based approach to observing, comparing, and classifying perceptual granules, as the study of It concentrates on the exploration of granulate affinities. A similarity of object definitions is the fundamental concept in the near-set approach to object recognition. Objects having the same appearance (objects with corresponding descriptions) are perceptively considered near one another. Many papers have appeared as a generalization of traditional near sets models such as [16, 17].

The key to an understanding of near sets is the notion of description. Each perceived object is represented by a vector of feature values and each feature is presented by a probe function that maps an object to a real value. Probe functions in near set theory provide a link between soft sets and near sets since every parameter in soft set theory is a particular form of probe function. It follows that we illustrate some important relations between soft relations and model near sets.

Alongside scientific advances and investigations, there has been a rise in the number of real-life implementations dealing with unclear, imprecise, contradictory, and confounding information in different fields in recent years [18]. Soft computing is a sophisticated form of computation that corresponds to the human intellect's extraordinary connection to intention and perception in an environment of imprecision and ruggedness to improve and strengthen the Inclusiveness of the real-life decision-making process [19–21].

We will present the concept of soft sets in this paper and then redefined some essential concepts of traditional near sets, based on soft sets, as soft near concepts. Basic properties of soft near approximations are deduced and proved. We developed a methodology to expect survival of the patient from soft near identified theory perceptions in lung cancer resections.

1.1. Lung cancer resections survival study

Lung cancer is the explanation for roughly 170,000 deaths of cancer within the U.S, accounting for nearly 25 percent of all cancer demises. More people die as a result of lung cancer per year than of the combination of colon, breast, and prostate cancer. The 5-year lung cancer mortality rate is 55 percent for diagnosed cases where the cancer is also located. The diagnosing of carcinoma at an initial stage is incredibly low (about 16%); also, more than 50% of lung cancer patients died before the first year after their discovery [22]. While early diagnosis and timely therapy are good for cancer patients' survival rates, the growing health-related issues are negatively impacted [23]. The combination of surgery, chemotherapy and radiation treatment has been improved on lung cancer treatment. Pneumonectomy is important to the administration of non-small cell lung cancer (NSCLC), but it is associated with high mortality rates [24]. Thus, patient's candidate for pneumonectomy must be considered cautiously in order to prevent surgical dangers [25].

Numerous factors are influencing the complication and mortality of malignant disease after pneumonectomy [26]. In [27] the author Analyzed the health history of 406 successive patients who experienced pneumonia to detect postoperative signs and risk factors affecting long-term survival. In [28] the author Discuss postoperative mortality in patients who have undergone pneumonectomy with vascular disease and find that they are significantly elevated. Complications occur or grow in all cases in those patients that have vascular or insulin related diabetes after surgery. In [29] the author proved that the high controlling nutritional status (CONUT) score, centered on some in peripheral blood that easily be calculated from blood examination data are a significant indicator of a One-year mortality rate in patients undergoing lung resection. The adverse survival factors after pneumonectomy, according to author in [30], involved older age, prolonged resections, advanced stage, postoperative nonlethal complications, adenocarcinoma, and others. Several articles have established gender and other demographic factors of people on lung cancer, and age, gender, tumor size, FEV1, histology, and tumor classification are significantly influenced by survival rate in this type of cancer [31, 32].

Surgical therapies prove to be an effective tool against lung cancer. If it is not possible to provide surgical resection, the death rate grows with all the diagnostic treatment.

1.2. Contribution and Organization of the Paper

Our approach was influenced by previous innovations of soft computing techniques for medical diagnosis. In [33] the author Used fuzzy set with soft set to predict a 5-year survival rate in lung cancer patients undergoing pulmonary resection. In [34] the author conduct a comparative medical prostate cancer diagnosis analysis using a multi-criteria decision-making approach in a fuzzy environment. In [35] the author presented solutions to improve the approach of soft rough sets and introduced a medical application about the Coronavirus “COVID-19” to illustrate the important solutions in decision making. In [36] the author Review rough and near-set methods to multiple medical imaging challenges.

In this work, we using the new method that depending on soft set with near set to determine not only classify a patient as mortality risk of one-year time for lung cancer patients or not, but also, to determine the degree of that risk. Also, we analyze its results and then conclude them in a diagram as a statistical representation. Finally, we support this application with the algorithm and some decision rules.

2. Preliminaries

In this section, basic definitions of information system, soft set, and near set approximations are introduced.

Definition 2.1 [37] $IS = (U, E, V, f)$ is called an information system, U is called universe and consist of a nonempty finite set of objects. E is a finite non-empty set of attributes, $V = \cup \{V_e, e \in E\}$, V_e is the value set of attribute e , and $f: U \times E \rightarrow V$, is called an information (knowledge) function or knowledge representation system and if $V_e = \{0, 1\}$, for every $e \in E$, then IS called a Boolean-valued information system.

Definition 2.2 [2] Consider U as an initial universe set, E as a set of parameters, $A \subseteq E$, and let $P(U)$ represent the power set of U . Then, a pair $S = (F, A)$ is named a soft set over U , where F is a mapping given by $F: A \rightarrow P(U)$. In other words, a soft set over U is a parameterized family of subsets of U . For $e \in A$, $F(e)$ It may be viewed as the set of e -approximate elements of S .

Definition 2.3 [11] An equivalence class of an element $x \in U$, determined by the equivalence relation E is

$$[x]_E = \{x' \in U: E(x) = E(x')\}$$

It follows that U/E , called the partition of U with respect to E , and it is defined as

$U/E = \{[x]_E: x \in U\}$. Let $A = \{E_1, E_2, \dots, E_n\}$ be a family of equivalence relations on U . Then $[x]_A = \{x' \in U: E_i(x) = E_i(x'), \forall E_i \in A\}$, and $U/A = \{[x]_A: x \in U\}$.

The following definitions and concepts of near sets are introduced by Peters in [12–14].

Definition 2.4 Let F represents a set of features of objects in a set X . For any feature $a \in F$, we associate a function $f_a \in B$ that maps X to some set V_{f_a} (range of f_a). The value of $f_a(x)$ is a measurement associated with a feature a of an object $x \in X$. The function f_a is called a probe function.

The study of near-set theory shows an interest in classifying samples using probe functions that are correlated with objects, for example, digital images, defined probe functions are color, shape, contour, spatial orientation, and line length segments through a bounded field.

Definition 2.5 $GAS = (U, F, N_r, V_B)$ is a generalized approximation space, where U is a universe of objects, F is a set of functions representing object features, N_r is a family of neighborhoods defined as:

$$N_r(F) = \bigcup_{A \subseteq p_r(F)} [x]_A, \text{ where}$$

$$P_r(F) = \{A \subseteq F : |A| = r, 1 \leq r \leq |F|\}$$

Definition 2.6 $N_r(B)$ -lower, upper approximations of a set X with respect to probe functions B , taken r at a time, are defined as

$$N_r(B)_* X = \bigcup_{x: [x]_{B_r} \subseteq X} [x]_{B_r},$$

$$N_r(B)^* X = \bigcup_{x: [x]_{B_r} \cap X \neq \emptyset} [x]_{B_r},$$

After previous definitions, Interesting relations between soft sets and near sets can be indicated. Near sets philosophy is dependent on information (data, knowledge) about every object of interest. For example, if consider the patients that have the certain illness are objects, symptoms of this disorder are features and then there exists a probe function for every symptom measuring the values of it. Hence, we get an information system, which can be regarded as a tabular representation of a soft set, its universe is the set of objects (patients) and its parameters are symptoms of a certain disease thus any soft set could induce an information system. On it, near set approximations can be redefined. For more illustration, Remark 2.1, is given

Remark 2.1 Let $S = (F, A)$ be a soft set over U . Hence, for all $a \in A$, there exists $F(a) = \{x \in U : a(x) = 1\}$. Consequently, we can consider every parameter $a \in A$ is a function $a: U \rightarrow \{0,1\}$, $a(x) = 1$ if $x \in F(a)$, otherwise $a(x) = 0$. Therefore, every soft set $S = (F, A)$ over nonempty set U can be considered as the information system (U, A) , corresponding to S .

Also, near set approximations may be redefined as soft near set approximations, based on the concept of soft set.

3. Soft near set approximations (SN-set approximations)

In this section, lower SN-approximations and upper SN-approximations are defined. Also, their properties are deduced and proved.

Definition 3.1 Let $S = (F, A)$ be a soft set over a nonempty set U . The elementary set, with respect to a parameter $a \in A$ is $F(a)$ means the set of objects having the property $a \in A$: Also,

$F(a, b)$ means the set of objects having the properties $a, b \in A$.

Remark 3.1 According to Definition 3.1, we can deduce that,

$$F(a_1, a_2) = F(a_1) \cap F(a_2) : \text{Consequently;}$$

$$\begin{aligned} F(a_1, a_2, \dots, a_r) &= F(a_1) \cap F(a_2) \cap \dots \cap F(a_r) \\ &= \bigcap_{i=1}^r F(a_i) \end{aligned}$$

This means the objects having all the properties $a_1, a_2, \dots, a_r \in A$.

Definition 3.2 Let $S = (F, A)$ be a soft set over a nonempty set U . The family of all elementary sets of U , with respect to all parameters A , taken only one parameter at a time, is

$$\xi_1 = \{F(a) : a \in A\}$$

Remark 3.2 According to Definition 3.2, we can deduce that the family of all elementary sets of U ; with respect to all parameters A , taken r of parameters at a time, is

$$\xi_i = \left\{ \bigcap_{i=1}^r F(a_i) : a_i \in A, 1 \leq r \leq |A| \right\}$$

For illustration, we consider the following example.

Example 3.1 Let us consider the following soft set $S = (F, A)$ Which identifies the conditions of patients suspected influenza, that a hospital is considering to make a decision. Suppose that the universe $U = \{p_1, p_2, p_3, p_4, p_5\}$, consists of five patients and $A = \{a_1, a_2, a_3, a_4\}$ is a set of decision parameters. The a_i ($i = 1, 2, 3, 4$) stands for fever, nasal discharges, headache and sore throat, respectively. The soft set $S = (F, A)$ over U , given by the following collection of approximations $\{\text{fever, } \{p_1, p_3, p_4, p_5\}\}$, (nasal discharges, $\{p_1, p_2, p_4\}$), (headache, $\{p_3, p_4\}$), (sore throat, $\{p_2, p_4\}$). It follows that,

$F(a_1) = \{p_1, p_3, p_4, p_5\}$, $F(a_2) = \{p_1, p_2, p_4\}$, $F(a_3) = \{p_3, p_4\}$, $F(a_4) = \{p_2, p_4\}$, $F(a_1, a_2) = \{p_1, p_4\}$, $F(a_1, a_3) = \{p_3, p_4\}$, $F(a_2, a_4) = \{p_2, p_4\}$, $F(a_1, a_4) = F(a_2, a_3) = F(a_3, a_4) = F(a_1, a_2, a_3) = F(a_1, a_2, a_4) = F(a_1, a_3, a_4) = F(a_2, a_3, a_4) = F(a_1, a_2, a_3, a_4) = \{p_4\}$. Hence, the families of all elementary sets of U are

$$\begin{aligned} \xi_1 &= \{\{p_2, p_4\}, \{p_3, p_4\}, \{p_1, p_2, p_4\}, \{p_1, p_3, p_4, p_5\}\}, \xi_2 \\ &= \{\{p_4\}, \{p_1, p_4\}, \{p_2, p_4\}, \{p_3, p_4\}\}, \xi_3 = \xi_4 = \{\{p_4\}\}. \end{aligned}$$

the soft set can be viewed as a boolean-valued information system corresponding to S , given by Table 1, as follows

Table 1 Boolean tabular representation of the soft set an Example 3.1.

	p_1	p_2	p_3	p_4	p_5
a_1	1	0	1	1	1
a_2	1	1	0	1	0
a_3	0	0	1	1	0
a_4	0	1	0	1	0

Definition 3.3 Consider $S = (F, A)$ as a soft set over a nonempty set U , and consider ξ_r as the family of all elementary sets of U , defined in Remark 3.2. Then (U, S, ξ_r) is called a soft near approximation space (SNAS) and for any subset $X \subseteq U$, lower SN-approximations and upper SN-approximations, respectively, are defined as

$$\underline{SN}_r X = \cup \{ Y \in \xi_r : Y \subseteq X \},$$

$$\overline{SN}_r X = \cup \{ Y \in \xi_r : Y \cap X \neq \emptyset \}$$

Definition 3.4 Let $S = (F, A)$ be a soft set over U , then (U, S, ξ_r) is $(SNAS)$ corresponding to S . For any considered set $X \subseteq U$ in (U, S, ξ_r) , the sets

$$Pos_r X = \underline{SN}_r X,$$

is named SN -positive region of the considered set X , with respect to all parameters taken r parameters at a time. The real meaning of $Pos_r X$ is the set of all elements, which are surely belonging to X , having r parameters.

Definition 3.5 Let (F, A) be a soft set over a nonempty set of patients U , A be a set of parameters measuring some symptoms of a certain disease, ξ_r be the family of all elementary sets of U , and let every parameter in A has the same importance in this disease. Then, we can measure the incidence of this disease, in any subset $X \subseteq U$, by the following concept

$$D_r(X) = D(\xi_r) d_r(X), \text{ where } d_r(X) = \frac{|pos_r(X)|}{|X|} \quad \text{and} \quad D(\xi_r) = \frac{r}{|A|}, 1 \leq r \leq |A|$$

It is easy to see that, this concept aims to discover the incidence of a certain disease in a specific area (surrounded region) to be able to take a suitable decision, in an obvious view.

The value of r is defined by disease type (here, r is the number of symptoms, which the person must have, to be a patient).

Example 3.4 According to Example 3.1, let the specific area be the set $X = \{p_1, p_3, p_4, p_5\}$ and let $r = 2$, then $pos_2(X) = \{p_1, p_3, p_4\}$ and then

$$D_2(X) = \left(\frac{3}{4}\right)\left(\frac{2}{4}\right) = \left(\frac{6}{16}\right)$$

It means that the set X is suffering from this disease with 37.5%. It follows that this set (specific area) needs some prevention of this disease.

4. Soft near set concepts (SN-set concepts)

In this section, certain definitions and properties of near-set principles are redefined.

Definition 4.1 Let (U, S, ξ_r) be $(SNAS)$ corresponding to a soft set $S = (F, A)$ and let $x, y \in U$. Then x is soft near to y , iff exists $a \in A$, such that

$$x, y \in F(a) \text{ and denoted by } x[Sn]_a y.$$

Note that, an element is not considered soft near to itself, because the basic idea of soft nearness is to compare object descriptions (in only, positive view of the parameters). Here, two elements are considered soft near each other if they satisfy, at least, one parameter of A .

Proposition 4.1 Let (U, S, ξ_r) be $(SNAS)$ corresponding to a soft set $S = (F, A)$ and let $[Sn]_a$ be a soft nearness relation, between

two objects with respect to a parameter $a \in A$, defined in Definition 4.1. Then, $[Sn]_a$ is an equivalence relation.

Proof Obvious.

Definition 4.2 Let (U, A) be an information system based on a soft set $S = (F, A)$. A subset R_i of A is called a reduct of A , if R_i is a minimal subset of A , such that $U/R_i = U/A$.

Definition 4.3 Let (U, A) be an information system based on a soft set $S = (F, A)$. If $U/[A-a] \neq U/A$, then the parameter $a \in A$ can not be canceled, and then we can define the core of parameters A , as follows

$$cor(A) = \{a \in A : U/[A-a] \neq U/A\}.$$

Thus

$$cor(A) = \cap \{R_i : R_i \text{ is a reduct of } A\}.$$

Definition 4.4 Let (U, A) be an information system based on a soft set $S = (F, A)$ and let $R = \{R_i \subseteq A : U/R_i = U/A\}$ be the family of all reducts of A . Then the weight of the parameter $a \in A$ is calculated by the following relation

$$w(a) = \frac{|\{R_i \in R : a \in R_i\}|}{|R|}$$

Proposition 4.2 Let (U, S, ξ_r) be $(SNAS)$ corresponding to a soft set $S = (F, A)$. For any parameter $a \in A$ the following hold

If $w(a) = 0$, then a can be canceled.

If $w(a) = 1$, if and only if $a \in cor(A)$.

Proof

Let $w(a) = 0$, then $|\{R_i \in R : a \in R_i\}| = 0$, and then for all reducts $R_i \in R$, we have $a \notin R_i$. Hence, $U/A \neq U/[A - \{a\}]$, it follows that the parameter $a \in A$ can be canceled.

Let $w(a) = 1$, then $|\{R_i \in R : a \in R_i\}| = |R|$, and then for all reducts R_i , we have $a \in R_i$. Hence, $U/A \neq U/[A - \{a\}]$, it follows that the parameter $a \in A$ cannot be canceled. Therefore, $a \in cor(A)$.

Conversely, let $a \in cor(A)$, then $a \in R_i$, for all $R_i \in R$, and then $|\{R_i \in R : a \in R_i\}| = |R|$, it follows that $w(a) = 1$.

Definition 4.5 Let (U, S, ξ_r) be $(SNAS)$ corresponding to a soft set $S = (F, A)$, and let $x, y \in U$. Then the soft nearness degree between two elements $x, y \in U$ is defined as follows,

$$r(x, y) = \sum \frac{\{w(a) : x[Sn]_a y, a \in A\}}{\{w(a) : a(x) = 1 \text{ or } a(y) = 1\}}, x \neq y.$$

Definition 4.6 Let (U, S, ξ_r) be $(SNAS)$ corresponding to the soft set $S = (F, A)$, and let $X, Y \subseteq U$. Then X is soft near to Y , iff there exists, $x \in X, y \in Y$ and $a \in A$, such that $x[Sn]_a y$, and it is denoted by $X[SN]_a Y$.

Remark 4.1 In Definition 4.6, if the set Y is replaced by the set X , then we can deduce that $X[SN]_a X$ if and only if there exists $x, y \in X$, such that $x[Sn]_a y$. It follows that a set X is called soft near

if and only if X is a nonempty set and contains two different elements, that are soft near each other to some degree.

Definition 4.7 Let (U, S, ξ_r) be (SNAS) corresponding to a soft set $S = (F, A)$, and let $X, Y \subseteq U$. Then the soft nearness degree between two sets $X, Y \subseteq U$ is defined as follows

$$R(X, Y) = \sum \frac{\max \{r(x, y) : x \in X, y \in Y\}}{|X|}, X \neq \emptyset$$

Proposition 4.3 Let (U, S, ξ_r) be (SNAS) corresponding to a soft set $S = (F, A)$, $x, y \in U$,

$X, Y \subseteq U$ and let r, R be the relations of soft nearness degree, defined in Definitions 4.5 and

4.7, respectively. Then, the following hold

$$r(x, y) = r(y, x)$$

$$R(X, Y) \neq R(X, Y).$$

$$\text{if } X \subseteq Y, \text{ then } R(X, Y) = 1.$$

$$0 \leq r(x, y) \leq 1 \text{ and } 0 \leq R(X, Y) \leq 1.$$

$$r(x, y) = 1 \text{ iff } a(x) = a(y), \text{ for all } a \in A.$$

$$R(X \cap Y, X) = R(X \cap Y, Y) = R(X, X \cup Y) = R(Y, X \cup Y) = 1.$$

Proof of Proposition 4.3, comes directly, from Definitions 4.1, 4.5, and 4.7.

Remark 4.2 In this paper, the notion of soft nearness is meaning near in, only, a positive view of the parameters. For more illustration, if we have a soft set, its universe contains some patients and its parameters are the symptoms of a certain disease. Here, two patients are considered soft near each other if there exists, at least, one symptom (parameter) such that these two patients suffering from it (near in their illness).

5. Materials and methods

5.1. Dataset

This research was based on data collected from patients with lung cancer referring to health care centers which are also available in UCI datasets [38]. This dataset was compiled retrospectively between the years 2007-2011 and was registered in the Polish National Cancer Registry. The dataset consists of 17 variables as seen and defined in Table 2.

470 samples are included in the dataset and there are 16 discrete inputs and one discrete output element. The qualitative or quantitatively of each of the features mentioned in Table 1. Two classes of 0 or 1, indicating death or life respectively.

As a preprocessing step, we selected the most significant attributes (performance, dyspnoea, cough, tumor size, and diabetes mellitus) of dead people after a year, and leaving people in the dataset was performed by author in [39] as shown in Table 3. The data includes two categorical variables are show in Table 4.

Table 2: Thoracic Surgery Data Set

Attribute	Description
Diagnosis	combination of (ICD-10) codes for Classification of Diseases
FVC	the patient's air volume will expire fast
FEV1	Final volume amount at the completion of the first second stage of induced expiration
Performance	Status of quality of life on Zubrod scale, Good (0) to Poor (2)
Pain	Pain, before surgery (T = 1, F = 0)
Haemoptysis	Coughing up blood, before surgery (T = 1, F = 0)
Dyspnoea	Difficulty in breathing, before surgery (T = 1, F = 0)
Cough	Cough, before surgery (T = 1, F = 0)
Weakness	Weakness, before surgery (T = 1, F = 0)
Tumor Size	T in clinical TNM - size of the original tumor, 1 (smallest) to 4 (largest)
Diabetes Mellitus	Type 2 diabetes mellitus (T = 1, F = 0)
MI_6mo	Patients with IM (Myocardial Infarction) over 6 months prior to surgery (T = 1, F = 0)
PAD	Peripheral arterial diseases (T = 1, F = 0)
Smoking	True = 1, Fals = 0
Asthma	True = 1, Fals = 0
Age	Age in year
Death_1yr	1 year survival period - (T) value if died (T = 1, F = 0)

Table 3: Most significant attributes

	Performance	Dyspnoea	Cough	Tumor_Size	Diabetes_Mellitus	Death_1yr
p_1	2	0	1	4	0	0
p_2	1	0	0	4	0	0
p_3	1	0	1	4	0	1
p_4	1	1	1	3	0	0
p_5	1	0	0	3	0	0

Table 4: Categorical data

Attribute Name	Attribute Value
Performance	Good (0) to Poor (2)
Tumor_Size	1 (smallest) to 4 (largest)

The encoding system scheme [40] converts categorical attributes into a format that effectively addresses algorithms for classification and regression. One hot encoding produces new

(binary) columns, indicating the presence of each possible value from the original data and represented by a vector where all elements of the vector are 0 except for one, which has a value of 1 as seen in Table 5.

Table 5: Boolean tabular representation of the soft set

	per_0	per_1	per_2	Dysp	Cough	TN_1	TN_2	TN_3	TN_4	Dia_M

5.2. Methodology

The algorithm is defined to measure the lung cancer mortality risk for patients after lung cancer resections in period 1-year based on 5 parameters. by New soft near set approach.

The Algorithm

1. Input the Boolean-valued information system corresponding to a considered soft set $S = (F, A)$ on U .
2. Compute the set $cor(A)$.
3. Consider the set $X = \cup \{X_i \in [U/cor(A) - U/A]\}$.
4. Compute every set of parameters $A_i \subseteq A$, such that $X/A_i = X/A$.
5. Compute all reducts $R = cor(A) \cup A$, for all A .
6. Input $A' = \cup \{R_i \in R\}$
7. Compute $w(a)$, for all $a \in A$.
8. Input the set $p = \{s_i\}$, such that $a(s_i) = 1$, for all $a \in R_i$.
9. Input the boolean-valued information system corresponding to (F, A') on P .
10. Compute $r(p_i, s_j)$ for all $p_i \in U, s_j \in P$.

11. Compute $R(\{p_i\}, p)$, for all $p_i \in U$, (the disease degree of the patient p_i).
12. Represent $(p_i, R(\{p_i\}, p))$ for all $p_i \in U$, in a statical model.
13. If $0.1 < R(\{p_i\}, p) \leq 0.5$, then p_i will be a survival patient.
14. If $0.5 < R(\{p_i\}, p) \leq 1.0$ then p_i will be dead in one year.

5.3. Algorithm: Application for survival analysis

Suppose that the universe $U = \{p_1, p_2, p_3, \dots, p_{20}\}$ consists of 20 patients and $A = \{per_0, per_1, per_2, Dysp, Cough, TN_1, TN_2, TN_3, TN_4, Dia_M\}$ is a set of condition parameters.

Step1: Input the Boolean-valued information system corresponding to a considered soft set $S = (F, A)$ on U as shown in Table 4.

Step 2: Compute the set $cor(A)$.

From Table 5, we can deduce that,

$$U/A = \{U/[A - per_0], U/[A - per_1], U/[A - per_2], U/[A - Dysp], U/[A - Cough], U/[A - TN_1], U/[A - TN_2], U/[A - TN_3], U/[A - TN_4], U/[A - Dia_M]\}.$$

It follows that, *Cough* and *Dia_M* cannot be canceled, then $cor(A) = \{Cough, Dia_M\}$ as it is show in Table 6, and then

$$U/cor(A) = \{\{p_2, p_5, p_7\}, \{p_{12}, p_{16}, p_{18}, p_{20}\}, \{p_1, p_3, p_4, p_6, p_8, p_9, p_{10}, p_{11}, p_{13}, p_{14}, p_{15}, p_{17}, p_{19}\}\}.$$

Hence, $X = \{p_1, p_3, p_4, p_6, p_8, p_9, p_{10}, p_{11}, p_{13}, p_{14}, p_{15}, p_{17}, p_{19}\}$.

Step 3. Consider the set $X = \cup \{X_i \in [U/cor(A) - U/A]\}$.

must be classified again by using the rest of parameters $[A - cor(A)] = \{per_0, per_1, per_2, Dysp, TN_1, TN_2, TN_3, TN_4\}$. For this end, given Table 7.

Step 4. From Table 4 Compute every set of parameters $A \subseteq A$, such that $X/A = X/A$:

$X/per_0, x/per_1, x/per_2, x/Dysp, x/TN_1, x/TN_2, x/TN_3, x/TN_4$; as the values of *all attributes* are not equivalent cannot be dropped any attribute, as a result we get Table 6 still without change.

Step 5. Compute all reducts $R = cor(A) \cup A$, for all A .

We compute 35 reducts of the parameters $A(R_i = A_i \cup cor(A))$

Step 6. Input $A' = \cup \{R_i \in R\}$ and step7. Compute $w(a)$, for all $a \in A$.

By using Definition 4.4, the weight of every condition parameter $a_i \in A$ can be calculated as follows:

$$\text{follows: } w(Cough) = w(Dia_M) = \frac{35}{35} = 1, \quad w(per_0) = w(per_2) = \frac{20}{35}, \quad w(per_1) = \frac{27}{35}, \quad w(Dysp) = \frac{34}{35}, \quad w(per_1) =$$

$$\frac{27}{35}, w(TN_1) = \frac{24}{35}, w(TN_2) = \frac{29}{35}, w(TN_3) = \frac{19}{35}, w(TN_4) = \frac{24}{35}.$$

The set of parameters A will be $A' = \{per_0, per_1, per_2, Dysp, Cough, TN_1, TN_2, TN_3, TN_4, Dia_M\}$ and the boolean-valued information system corresponding to the soft set $S' = (F, A')$ can be presented in Table 4.

step 8 and step 9: Input the set $p = \{s_i\}$, such that $a(s_i) = 1$, for all $a \in R_i$. And Input the boolean-valued information system corresponding to (F, A') on P .

Let $p = \{s_1, s_2, \dots, s_{35}\}$ be the set of standard patients, in which every patient satisfies all parameters in one reduct of A . The soft set (F, A') on P , is given in a tabular form, in Table 8.

Step 10. Compute $r(p_i, s_j)$ for all $p_i \in U, s_j \in P$.

By using Definitions 4.1 and 4.5, the soft nearness degree between p_1 and s_1 in a soft set $S' = (F, A')$ over the set $(U \cup P)$, can be calculated as follows.

Table 9 introduces soft nearness degrees between every element in the universal set U and every element in the set of standard patients P ,

Step 11. Compute $R(\{p_i\}, p)$, for all $p_i \in U$, (the disease degree of the patient p_i). From Table 9, we can deduce Table 10, where $s_i \in p$.

Step 12. Represent $(p_i, R(\{p_i\}, p))$ for all $p_i \in U$, in a statical model.

By using Definition 4.7 and Table 9, the nearness degree between singleton set $\{p_i\}$, for all $p_i \in U$ and the set of standard patients P ; can be calculated and arranged in Table 11.

To analyze these results, we can draw Figure 1, as follows Patients

Let the degree of the survival for a patient p be λ . From Diagram 1, we can deduce the following decision rules

If $0.1 < \lambda \leq 0.5$, then p_i will be a survival patient.

If $0.5 < \lambda \leq 1.0$ then p_i will be dead in one year.

6. Results and discussion

The classification accuracy is the percentage of findings accurately estimated by the method. It was used to measure each algorithm's efficiency.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

where TP (True Positive), TN (True Negative), FP (False Positive), and FN (False Negative).

From Table 12 that contains the actual diagnosis from the dataset and the predicted diagnosis from the expert system. Table 13 shows the confusion matrix and the accuracy is 90%.

In our work, we introduced an expert system to estimate the mortality risk to Patients of pulmonary resection for lung cancer in a period of one-year. We have used a new concept depending

on combined soft set with near sets, which is part of the field of soft computing development that is very effectively used to deal with the confusing or uncertain information that we always identify in the available data. the model takes into account five entry variables (performance, dyspnoea, cough, tumor size, and diabetes mellitus) and produces the 1-years mortality risk as to the expert system output. Accurate classification for one-year survival achieved 90.0%.

The Risk scale can determine that patients p1 with risk 0.401 and p2 with risk 0.277 for example, as not death cases and the model classified it correctly as shown in Table 12, but that tell for experts that p1 has high risk more than p2 and needs more care.

In addition, certain current documents using the same dataset were also comparable with the work suggested. Table 14 Provides the study findings, in fact, the classification accuracy of the proposed Method surpassed all recently suggested.

Table 13: Matrix of confusion for our survival test

	Predicted positive	Predicted negative
P =Actual positive = 9	(TP) = 8	(FN) = 1
N=Actual negative = 11	(FP) = 1	(TN) = 10

Table 14: Performance comparison of the proposed method with existing techniques by the same dataset

Author(s)	method	Best accuracy
[41]	Used ranking (information gain, Symmetrical Uncertainty, Relief-F) methods before Naïve Bayes, Simple Logistic Regression, J48, and Multilayer Perceptron techniques.	84.53
[42]	Used multi rule-based methods results have shown that the ZeroR method has the best classification accuracy.	85.10
[43]	Used feature selection method (Crow search algorithm (CSA) and K nearest neighbor (KNN) classifier.	83.64
[44]	Used feature subset selection method with Random Forest (RF) classifier.	86.88
Proposed method	Used soft- near proposed technique.	90.0

The primary database contains 470 patients with lung resection, we configure our expert system with 20 patients selected randomly from the total existing data and 90.0 percent accuracy has been achieved.

We are investigating that our soft near set novel version is an effective and accurate diagnostic application for determining the 1-year survival rate in lung cancer patients.

7. Conclusion

In this paper, we have presented the notion of soft near sets, which can be viewed as a hybrid model combining near sets with soft sets. It leads that, the proposed model is more effective and useful in a decision-making problem. Some fundamental concepts have been defined and their basic properties have been deduced and proved. Finally, we have presented an application of the suggested model for the decision-making of patients' lung cancer. In it, we succeeded in getting the Risk scale for every patient, and then we deduced some decision rules.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Worldwide, the epidemiological situation is constantly changing and with the exponential increase in the number of confirmed coronavirus cases, the number of health care workers has decreased significantly and this is due to the direct and daily contact of patients. One of the major challenges of the last few months is to prevent the spread of the new Covid-19 virus. The most recommended solution to this problem is telemedicine, which brings benefits in terms of reducing healthcare expenditure, improving the quality and safety of care, in order to protect healthcare workers from the risks of contamination and reduce the constraints related to patient shifting. This document presents our thoughts on how to guarantee the safety of healthcare workers, by implementing an application based on wireless sensor networks with introducing the 5G technologies to satisfy high-speed transmission. This involves transmitting medical data from several sensors placed on the patient's body, which measure physiological signs in real time, to the hospital server via the Internet, to produce medical information useful for diagnostic and monitoring purposes. Therefore, the doctor will be able to consult and analyze the patient's medical file through a communication interface between the patient and the doctor developed in JEE, as it can receive an SMS in case of emergency.

1. Introduction

On January 9 2020, the world has known the emergence of a new coronavirus officially called SARS-CoV-2. This new virus has been identified for the first time in the city of Wuhan in China in December 2019. This new infectious respiratory disease called Covid-19 [1] spread rapidly in China and several other countries within six months after its appearance, infecting more than 188 countries and territories around the world. As of December 2020, nearly 70 million people were infected and 1.6 million people have died worldwide since the beginning of the pandemic [1]. In April 2020 the countries with the most reported physician deaths were Italy (44%), Iran (15%), Philippines (8%), Indonesia (6%), China (6%), Spain (4%), USA (4%) and UK (4%) and yet healthcare professionals must continue to face the health crisis [2].

Every person working in the health sector has the right to be safe and every sick person has the right to receive the appropriate treatment and care. In this respect, the best solution is to opt for telemedicine in order to reduce the risk of contamination while avoiding direct contact between patients, professional healthcare,

and managing asymptomatic cases or symptomatic patients from their homes.

The objective of our article is to present the new technologies used in telemedicine, thus, we propose to ensure the continuous monitoring of patients by introducing 5G technology to ensure the coverage of necessary medical care remotely, regardless of the patient's geographical location, and also to meet the requirements of high-speed transmission of massive multimedia medical data. At the same time, this architecture can be valuable to protect and provide a healthy and safe working environment for healthcare workers and reduce the pressure on health centers which can no longer accommodate infected people.

The proposed system is equipped with the most commonly used medical sensors in the clinic for diagnosing and monitoring patients, such as Electrocardiograph (ECG), Oximeter and temperature sensors that are linked together to form a wireless network using communication protocols such as ZigBee. These sensors are managed by the TinyOS system, which is the most widely used system in sensor applications today. This system is used to check the patient's state of health whether he is well or not

*Corresponding Author: Majda Lakhal, majdalakhal@gmail.com

by analyzing the medical signals collected from the sensors. If the results of the analysis are abnormal, an SMS containing the measured values and the patient's details will be sent by the server to the healthcare professional to save his or her life.

To consult and analyze the patient's medical record, an application in JEE programming (struts 2, hibernate 3, MVC 2, JavaMail and DisplayTag) is already developed by our team. It offers to cardiac patients a space for communication, consultation and medical monitoring. The proposed architecture is an additional module to store in the patient's database measurements taken in real time by the sensors.

2. Telemedicine Serving Populations

Telemedicine is a remote medical practice using information and communication technologies to provide home monitoring of patients by one or more health professionals. It can be carried out using any technological means currently available such as computer, mobile phone or tablet equipped with Internet connection. Also, we can set up developed devices that can-do detection, data processing, networking and communication to facilitate to the caregiver to monitor patients by receiving the necessary information.

2.1. Monitoring devices used in telemedicine

E-stethoscope is one of the devices designed for routine monitoring of heart disease, it has been developed for real-time cardiac monitoring, this device performs pre-processing and signal supply, and allows to display these signals on the LCD screen. In addition, data can be transmitted to the PC via Bluetooth or a serial port, in order that the doctor can diagnose from his computer. This device is suitable for assisted healthcare, its advantage is to reduce the frequent contact of the patient [3].

There is also a new stethoscope that can be connected to a smartphone that allows patients to use this device from home, as they can perform various tests on the signals observed using a mobile application and send data to a doctor for diagnosis [4].

The developers have designed a more advanced monitoring system that can monitor patients who have chronic diseases, in real time, such as heart rate, blood pressure, diabetes and it can even measure temperature, it also has the ability to store data and alert doctors to quickly intervene in case of emergency [5].

For elderly patients, a biosensor is used to monitor vital signs in real time and can even detect the patient's location. This portable system is used to collect physical data. This data is then transmitted to the intelligent server via GPRS (General packet radio services) for further analysis [6].

Smart beds are a highly recommended solution at this time because they contain biosensors for respiration, temperature and heartbeat that allow doctors to monitor patients remotely. The data can be reviewed for sleep, heart rate and respiratory rate analysis. In emergency situations, these devices can generate an alarm or send an alert to caregivers for immediate intervention [7].

For patients who are monitored remotely or who receive treatment at home, Sivaraj and other developers proposed an idea of an intelligent ambulance in order to reach hospitals faster. This ambulance is equipped with devices that observe the vital signs of a patient and send the information to the hospital for prearrangement. It also contains a system that can automatically change the traffic lights. Another study aims to find the fastest route for the ambulance [8].

In order to prevent the spread of the virus a technique of real-time detection of facial disorders has been proposed by installing devices at the entrance of hospitals, schools or public places. The technique offers a great potential for monitoring and surveillance and it is useful for colds, flu and detection of facial temperature, which allows the identification of people with contagious diseases [9].

3. The Wireless Sensor Network

The wireless sensor network is a field composed of sensor nodes as shown in figure 1. Each node has the capacity to collect information and transmit it to the node, which then transfers this information via the Internet or satellite to the central computer to study and analyze the data.

In the field of Internet of Things applications, sensor networks are made up of sensor devices which is an organ that collects information from physical quantities (temperature, force, position, speed, brightness) to transform them to a digital signal.

Figure 1: WSN Architecture

3.1. Transmission techniques of a WSN

Operations on networks around the world require transmission media. The main transmission techniques used are radio communication, infrared media and optical media. To deploy a large number of sensors we need maintenance of the network topology. This maintenance consists of three phases: Pre-deployment and deployment phase (installation of sensors), Post-deployment phase (some sensors may fail), Phase of redeployment of additional nodes (replace failed nodes).

3.2. Wireless sensors in different fields

In many fields, we need to monitor physical parameters in order to study and monitor phenomena, events or diseases [10].

- **Military field:** There are military applications for battlefield surveillance, recognition and detection of nuclear, biological and chemical attacks...
- **Agriculture:** implement sensors in the soil to measure humidity, temperature, etc.
- **Environmental control:** WNS built to study complex phenomena such as earthquakes, volcanoes and storms...
- **Health-related applications:** these applications allow the monitoring and surveillance of a disease progression, the implementation of sensor nodes in the patient's body for real-time diagnosis, blood glucose monitoring, early detection of cancers, etc. [10]

3.3. Wireless body network and the main sensors used in the medical field

A WNS in the medical field is known as a WBAN. This Wireless Body Area Network (WBAN) is a network that provides continuous monitoring of the human body through sensors located inside or outside a body to take measurements and transmit them to the base station. It allows the information collected to be shared anytime and anywhere over a long period of time. We find in the Table 1 the main sensors most used in medicine.

Table 1: The most used sensors in medicine

SENSOR	DESCRIPTION
Electrocardiogram	The Electrocardiogram (ECG) records the electrical activity of the heart. It is used to diagnose heart disease or to monitor heart rhythm disorders.
Electromyogram	The Electromyogram (EMG) is used to diagnose the functioning of nerves and muscles by means of electrical impulses.
Electroencephalogram	The Electroencephalogram (EEG) measures the electrical activity of the brain by attaching small electrodes to various locations on the scalp.
Blood glucose	This sensor measures the concentration of glucose in the interstitial fluid (interstitial glucose).
Temperature sensors	It allows to measure the temperature of the human body
Oximeter	The Oximeter allows to measure in real time and continuously the concentration of oxygen circulating in the arteries. It is used to monitor patients who have respiratory problems.
Blood pressure	The blood pressure sensor is used to measure diastolic and systolic pressure.
Accelerometer	This sensor is used to recognize the posture of the body (standing, sitting, kneeling, walking, running ...).

4. Architecture of the proposed solution based on wireless sensors

Figure 2 represent the architecture proposed in our project is applied on some patients with corona virus and who have chronic

diseases. It can also be applied on patients who have other chronic diseases, the difference will be just in the choice of the sensor.

The WBAN network can be divided into 3 sections. The first section represents Intra-BAN communication, which is a communication between the sensor node and the personal server. The sensor node stores physiological data retrieved from the sensors placed on the human body and then transmits them via a wireless network to a central processing device known as the personal server. The second section represents Inter-BAN communication, it is done between the personal server, which can be a cell phone, a personal assistant (PDA) or a personal computer, and the access point. Communication between the access point and the medical team via 5G connection represents the third section, which is the communication outside the BAN.

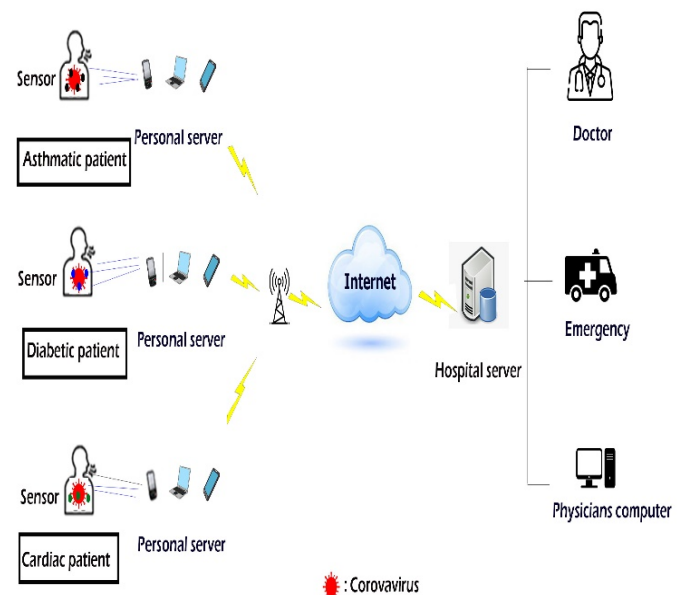

Figure 2: Architecture of the proposed solution based on wireless sensors

The electronic medical records of patients are stored in the hospital server, which can also provide various services such as user authentication, recognition of health anomalies, transmission and sending of emergency alerts to medical staff. The patient's doctor can access the patient's data from his PC via the Internet and examine it to ensure that the patient is complying with the expected health parameters (temperature, heart rate, blood pressure, etc.).

In the case of a cardiac patient with corona virus and respiratory problems, we will need a body temperature sensor that will be placed on the patient's hand to measure the body temperature, a sensor that measures the concentration of oxygen flowing in the arteries, placed on the patient's finger as with the pulse oximeter, and we will also need sensors that allow us to record the electrical activity of the heart. Their location will be like the location of the electrodes of the ECG to have the exact data.

4.1. Communication protocols

Among the most used wireless communication protocols that allow data transmission in networks are WiFi, Bluetooth, Zigbee.

ZigBee is designed to manage short distance communications, it range of 300 meters and it offers low energy consumption, it has three radio bands that operate in 868MHz, 915MHz, and 2.4GHz and it can accommodate up to 6000 devices [11].

Bluetooth is based on the IEEE 802.15.1 standard, it preferred in the case of a system whose interoperability is essential and whose autonomy may be limited, it ranges of 10 meters [11]. Wifi is based on the IEEE 802.11 standards, it operates in 2.4GHz and 5GHz bands and it requires high power and has the advantages of a high data rate and long distances [11].

4.2. ZIGBEE protocol

In our system we have opted for ZigBee technology which is an "open source" network, it is the most widely used in medical monitoring applications. It is supported by the IEEE802.15.4 standard, which standardizes two basic PHY and MAC layers of the network, which are layers 1 and 2 of the OSI model, and is a wireless data transmission standard allowing machine-to-machine communication at very low cost, low data rates, small footprint and with very low power consumption [12].

The Physical Layer (PHY) is the lowest layer defined in the IEEE 802.15.4 standard. This layer translates the frames sent and received into bits and manages the use of radio transmission and channel communication [13].

The role of the MAC layer is to control access to the radio channel via the CSMA/CA (Carrier Sense Multiple Access with Collision Avoidance) mechanism. This includes coordinating access to the common radio link and scheduling and routing data frames. Using the CSMA/CA mechanism is an access method used on bus topologies. Its purpose is to avoid collisions and to detect them if they occur [14].

The ZigBee protocol uses only four of the seven layers of the OSI model. It includes a Physical (PHY) layer that contains the radio frequency (RF) of the transceiver and its low-level control mechanism, and a MAC (Medium Access Control) sublayer that provides access to the physical channel for all types of transfers. The upper layers consist of a NWK (Network Layer), which provides network configuration, message handling and routing, and an APL (Application Layer), which is equipped with two APS (Application Support Sub-Layer) sub-layers, which is in charge of managing the mapping table used to associate the devices with each other and the ZDO (Zigbee Device Object) entity, which is responsible for defining the role of an object in the network and securing the relations between the devices [15].

4.3. Why choose the 5g technology?

Compared to other generations of wireless communications, 5G offers advantages in terms of low latency, high reliability and

mobility, providing an excellent opportunity to the development of telemedicine [16].

Telemedicine based on 5G technologies integrates the wireless communication technology of intelligent equipment and high-speed mobile communication technology in different modes, which can perform remote surgery, remote consultation, patient monitoring, decision making in case of emergency rescue. In addition, 5G-based telemedicine can also support the high-speed transmission of massive multimedia medical data, and further realize the sharing of medical resources.

5G networks are built around three development axes [17]:

- Speeds: in the continuity of current networks and to cope with the increasing demand of traffic, 5G networks will need to be able to achieve speeds up to ten times greater than in 4G.
- Latency: The response time of 5G networks will be divided by 10 to allow the development of new uses such as the autonomous car or telemedicine.
- Density: 5G embeds the Internet of Things (IoT) and will therefore have to manage millions of connections.

4.4. TinyOs and there Simulation tools

TinyOS [18] is an operating system designed for wireless sensor networks, developed by the American University of BERKELEY, which works in an event-driven mode (i.e. it only becomes active when certain events occur). It has the advantage of allowing simple and powerful programming while keeping the portability of the code for many supported platforms. Its design has been entirely made in NesC [19], a component-oriented language that is syntactically similar to the best known language C. TinyOS has been created to meet the characteristics and requirements of sensor networks, such as: Small memory size, low power consumption, intensive support operations, robust operations and is optimized in terms of memory and power usage.

TinyOs offers Simulation tools [20] (TinyViz /Tossim / PowerTossim)

- TOSSIM is the simulator of TinyOs. It is a simulator / emulator with discrete events of wireless sensor network. It gives us an idea on the network operation, transmission/reception, radio links between nodes, error messages, etc.
- PowerTossim allows to model the energy consumption of an application. It performs simulations in the same way as TOSSIM except that it takes into account the power consumption.
- TinyViz is a graphical application that gives an overview of our network of sensors at any time, as well as the various messages they emit. The application allows a step-by-step analysis by activating the different available modes, it also has options to simulate energy consumption.

4.5. The functioning and the placement of sensors ECG

The standard peripheral electrodes are placed as shown in figure 3, they explore the cardiac electric field in a frontal plane.

On the posterior aspect of the wrist joint place the red electrodes on the right and the yellow electrodes on the left and on the inner aspect of the ankle joint place the black electrodes on the right and the green electrodes on the left [21].

Figure 3: Peripheral electrode location [22]

These electrodes define 6 leads as shown in figure 4: 3 bipolar leads, I records the potential changes between the left arm and the right arm, II records the potential changes between the right arm and the left leg, and III records the potential changes between the left arm and the left leg. The other 3 leads (aVR, aVL, aVF) are unipolar. They record the same phenomenon, but in relation to a reference zero, obtained by a mounting device (Wilson bridge).

Figure 4: Direction of peripheral branches and angles separating them [21]

In addition to the peripheral electrode, there are the precordial electrodes which are placed on the costal grid as shown in figure 5. They are arranged on a horizontal plane to explore different parts of the ventricles, each electrode being placed at a different location [23] :

- V1 is placed in the right parasternal position at the edge of the sternum.
- V2 is symmetrical to V1 with respect to the sternum in the left parasternal position.
- V3 between V2 and V4

- V4 5th intercostal space and it's placed in the mid-clavicular line.
- V5 on the anterior axillary line between V4 and V6
- V6 is on the middle axillary line,
- V7 on posterior axillary line,
- V8 under the tip of the scapula and even horizontal as V4,
- V9 halfway between V8 and the posterior spines .
- V3R symmetrical to V3
- V4R symmetrical of V5

Figure 5: Location of the electrodes on the costal grid [24].

Figure 6 is a graphic representation of the electrical activation of the heart using an electrocardiograph, for each lead an ECG trace is recorded, 12 leads are classically recorded on the ECG trace and can be extended to 18 leads under certain circumstances.

Figure 6: ECG Signal [22]

This activity is collected on a patient lying down, at rest, by electrodes that record electrical signals (deflections) placed on the surface of the skin. In order for an ECG to be normal, several points must be present, among which are [23]:

- In adults The normal heart rate (coming from the sinus node in the right atrium) is a regular rhythm with a sinus rate between 60-100/min. Below 50/minute it is called bradycardia and above 100 it is tachycardia.

- Each sinus P wave precedes each QRS to detect conduction disorders between the atria and ventricles.
- The space between two QRSs must always be the same, which indicates that the heart rhythm is regular.
- The morphology of the atrial P wave and the ventricular QRS complex should be normal.
- The P-R (or P-Q) interval has a constant duration (0.12 to 0.20 s).
- QRS have a frontal axis between -30 to 90° .
- The ST segment is isoelectric to the PQ segment.
- The T wave is asymmetric and positive and its maximum amplitude $< 2/3$ of QRS and minimum $> 10\%$ of R.

4.6. The operation and the position of an oximeter

In the intensive care setting, oximeter is one of the most widely used monitoring tools in intensive care units, operating rooms and at the patient's home to monitor sleep disorders. It distinguishes arterial saturation from hemoglobin in O₂ [25]. The oximeter is often placed on the fingertip such as figure 7, which is very well vascularized, it can also be placed on the nose, ear or toe.

Figure 7: Optical setup [21]

The sensor contains two diodes emitting red light, the principle is based on the emission of two lights (red and infrared) [25], respectively 660 and 940 nm.

The absorption of the red and infrared light will vary depending on whether it encounters reduced non-oxygenated hemoglobin (Hb) or oxyhemoglobin (HbO₂).

The information collected by the temperature sensor, oximeter and cardiac disorder sensors will be collected and transmitted to the hospital server after having gone through the steps shown in Figure 2.

5. Healthcare platform

In order for doctors to be able to consult and analyze the patient's medical record, we need a medical platform reserved for patients and healthcare professionals with access rights granted by the administrator who is responsible for maintaining the

www.astesj.com

application and managing user accounts. He ensures the proper functioning of the data server and its security.

Once authentication is accepted, the doctor will be able to retrieve a specific patient's medical file containing all the information necessary for the patient's care and monitoring. The patient's record is not just the written observation of the doctor or the notes of the nurse. It encompasses everything that can be stored in a patient's file: administrative, clinical, paraclinical, diagnostic, therapeutic, preventive and prognostic data as well as the intervention of all those involved in the care of the patient.

The application also offers a communication space to keep contact between the patient and the doctor via correspondence or notification. Figure 8 represent the platform's interface developed by our teams.

Figure 8: platform's interface [22]

6. The relevance of the proposed solution

The coronavirus disease (COVID19) has been a major concern because of its very rapid spread in many countries. The statistics in the figure 9 show the number of people infected and dead by the coronavirus worldwide as of March 1, 2021. Out of a total of 113,820,168 confirmed cases of virus-related infections, 2,527,891 died [26].

Figure 9: Number of infections and deaths due to COVID-19 worldwide [26]

This contagious and deadly disease also exposes the medical profession to major risks. On May 8, 2020, the total number of healthcare workers reported infected was 152,888 and 1413 deaths worldwide (as shown in figure 10 and figure 11). This suggests that for every 100 healthcare workers who were infected, one died. The number of infected healthcare workers represents 3.9% of the total number of 3,912,156 patients with COVID-19 and the number of healthcare workers who died represents 0.5% of the total number of 270,426 deaths by COVID-19 worldwide. It should be noted that 118,801 of these patients with COVID-19 and 2,922 deaths were reported in countries where data on healthcare worker infections and deaths were not available. A total of 130 countries reported at least one case of COVID-19 infection among healthcare workers and 67 countries reported at least one healthcare worker death related to COVID-19. China and Italy were the first two countries to report health worker deaths due to Covid-19, and the first deaths in each of these countries occurred more than one month apart [27].

Figure 10: Number of reported COVID-19 infections in healthcare workers worldwide [27]

The high rate of infected patients requiring follow-up has exhausted the efforts of the medical staff and the number of hospital beds. Statistically, the majority of countries with hospital bed data are in the range of 0 to 299 hospital beds per 100,000

population. As shown in the figure 12, 79 (43%) countries had less than 200 hospital beds per 100,000 population, while 37 (20%) countries reported between 200 and 299 hospital beds per 100,000 population and only 13 countries (7.1%) reported more or equal to 700 beds per 100,000 population. For countries shaded in grey, data on the number of hospital beds are not available [28].

Figure 11: Number of reported COVID-19 deaths in healthcare workers worldwide [27]

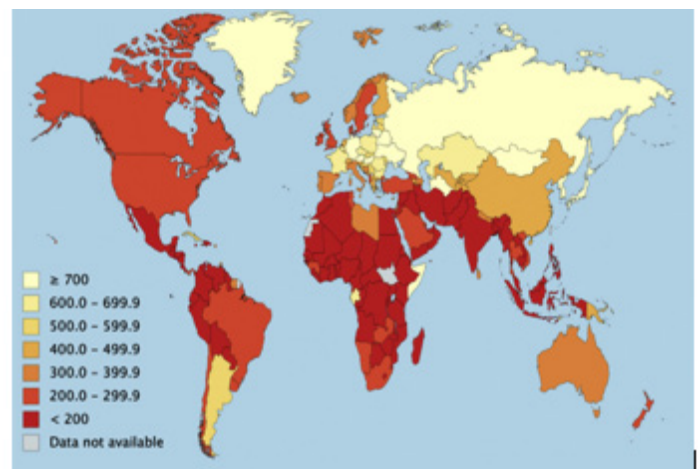

Figure 12: Number of Hospital Beds per 100,000 Population [28]

With regard to the points mentioned, which mainly concern the life of the medical staff, the conditions of their work, and the capacity of the hospital centers, our solution seems to be very important which will limit the infection of the staff, absorb the wave of hospitalizations of patients suffering from COVID-19 and continue to take care of those suffering from chronic diseases.

7. Conclusion

Around the world, doctors, nurses, caregivers, administrators and paramedics work in stressful and frightening environments and risk their lives to save their patients. Much scientific and clinical research has been proposed to control patients infected with COVID-19 but knowledge of this disease remains incomplete and evolving, posing an ongoing challenge to our understanding and clinical management. Therefore, the proposed

architecture for remote patient monitoring based on the wireless sensor network and 5G technologies will reduce patient travel and frequent contact with physicians while obtaining the necessary medical care. Healthcare workers will be able to perform a global assessment of the patient through the physiological information retrieved from the sensors placed on the patient's body that will be transmitted to the hospital server that will interpret and send it to the doctors. The future extension of this work consists of implementing this architecture using a simulator in order to apply it to real patients.

ABSTRACT

In recent years water treatment methods under pressurized systems have been considered as the optimum high-rate filtration techniques. Unpressurized-slow sand filtration can be the cheapest and most efficient method, among others. This research aims to test the performance of a reliable seawater filtration system, using three different iterations. The filters have been designed considering many types of filtration layers such as sand, gravel, palm chlorophyll and other layers. The results of routine tests showed that the seawater pH, and TSS, and conductivity in the Gulf of Oman are relatively high. The pH values were decreased from 9.4 to 8.4 (filter 1), 9.0 (filter 2), and 8.7 (filter 3). Filter three has a reduced value of conductivity from 13.06 to 12.81 Ms/cm while a slight increase in filters 1 and 2. The TSS values were significantly reduced from 12.42 mg/L to 1.682 mg/L (filter 1), 2.478 mg/L (filter 2), and 1.200 mg/L (filter 3). This reflects the efficiency for each filter for this parameter is 86.5% for filter 1, 80% for filter 2, while 90.3% for filter three. Water velocity through each layer was monitored using Darcy law where the water of filter three has the longest residence time and slowest flow per time. The fastest flow was in filter one with an average of 0.5 L/minutes, filter two has an average flow of 0.088 L/minutes, while filter 3 has a flow rate of 0.026 L/minutes. The third filter has provided the best performance according to the results. Statistical analysis was conducted to understand the correlation between different parameters. As per Pearson correlation, there is a significant correlation between pH and conductivity values for 19 samples (0.989), while the correlation with TSS is relatively weak (0.364).

1. Introduction

Oman lies in an arid climatic strip where the fresh water is limited [1]. Most of desalination processes in the country based on pressurized systems which require huge amount of energy and cost. Many kinds of particles can be found in seawater such as organic materials, suspended and dissolved solid coupled with high turbulence. Slow sand filtration is a method used for hundreds of years to produce better quality water [2]. In general term, water purification is a process of removing pollutants from water mainly to produce water for human use while the process can also be extended for various other purposes including agricultural and industrial needs especially in regions where water resources are limited. Depending on the sources of raw water, particle removal can be accomplished through physical, chemical, and biological processes [2]. However, slow sand filtration used

mainly physical process such as sedimentation and adsorption starting by removing fine particles to some organic matters. Because of the slow flow rates within the filtration media, the raw water sits above the sand for several hours before passing through [3]. Slow sand techniques are considered to be an proper for small scale systems such as farms and houses since the operating procedure and maintenance are simple [4]. As slow sand filters are simple, efficient, and economic, they are appropriate methods of water treatment in developing countries [5]. The purification efficiency of water in slow filters is high where the rate of removal turbidity may reach 100%, bacteria removal ranges between 89% and 99% [6] while the removal of color of 20-30% and 60% iron compounds [7].

Biological process is essential in the slow sand filtration operation, which is based on fine sand particles ranging from 0.15 to 0.35 mm [8], a bed thickness of 0.8 to 0.9 meters [9]. In [10], the authors summarized the advantages of using slow-sand filters

*Corresponding Author: Eyad Abushandi, Civil Engineering Stream, Faculty of Engineering, Sohar University, 0096891273733, Email: eabushandi@gmail.com

in two major points: first, acceptable levels of treated water quality, and second, low cost and easy of construction. While the disadvantages of slow-sand filters were cited by [11]:

- Not efficient in filtering viruses
- No protection against chemicals, especially chlorine which may lead to recontamination
- Routine cleaning can damage the bio-layer and reduce efficiency
- Not easy to move the unit into another place due to the weight and initial cost of installation.

In addition, slow sand filtration treatment unit will occupy a large area of land and require more control tests on a regular basis, which means more labor is required during cleaning process. In some tropical climates, there is a risk algae grows which will proliferate in slow sand filters causing filter blocking, change water taste and odor [12]. Sand filters may consist different layers and depths of sand, gravel, and activated carbon. In fact, there are different hypotheses on the depth of each filter layer based on the efficiency and amount of water required. In some cases, the depth of the sand layer can reach 2.5 m, while in compressed units or compressed filters; the depth of sand layer is not more than 1.2 m and not less than 80cm for required efficiency [13].

In [14], the authors tested new granular materials for dual-media bed filtration of seawater and to assess the quality of the filtrate regarding criteria for feeding reverse osmosis desalination installations. Two different filter columns, one with the new materials namely clay and Mono Multi filter, and another filter with anthracite coal 1.2–2.5 mm on upper part of a sand layer 0.8–1.25 mm. However, both filters had similar performance in removing particulates and producing filtrates of acceptable quality. In fact, the authors studied the impact of relatively high or low temperature gradients simulating summer and winter conditions. A formation of larger aggregates occurred in the column where the temperature is higher, thus reducing the flow rate and hydrostatic head. While the impact of the materials physical properties played a key role, the authors concluded that the higher temperature (summer) campaigns performed better.

In [15], the authors investigated the nature of the biological accumulation in filters during the filtration process of North seawater. The biological accumulation of two different types of filters (coarse, 80 μm and fine 5 μm) was investigated over a 24-months duration. They assessed the seasonality effect, particularly; temperature during cold and hot seasons on the accumulation of both organic and inorganic materials showed that the filter life in hot seasons is shorter due to higher biological activities. The research of [16] was conducted to assess the viability of slow sand filter using dolochar to filter waste water from an industrial source. Efficiency of slow sand filters was assessed using two laboratory conditions. A dual media filter showed higher removal ability, particularly, average chemical oxygen demand removal of up to 80.96% compared to 64.68% of a single sand media filter, and turbidity removal of 91.13% compared to 82.27% of a single sand filter. In addition, the total suspended solids (TSS) removal efficiencies of sand and dolochar media filter 89.08%, while in the single sand media filter removal efficiency was 82.48%. The authors concluded that the dual media filter which includes a

biofilm layer has better performance in comparison with a single sand media. The performance of slow sand filters in removing bacteria was carried by [17]. They study the physical properties of the layers mainly the grain size distribution and grain shape intermittently. Bacteria removal was conducted using two different filter media namely Rhine sand-spherical shape and Lava sand-angular shape with three different particle size distributions. A better achievement was observed by the filter unit which included lava sand layer. This result reflects the effect of smaller grain size and an angular shape of sand grain lead which lead to an increase in bacteria removal.

The research carried by [18] demonstrated the ability of slow sand filtration as tertiary treatment operating with municipal wastewaters. At a laboratory scale the filtration process was capable to remove at least 90% of suspended solids, over 65 % of BOD, and more than 95 % of the bacteria. As per the study physical properties of the layers plays a major role in removing contaminates. In addition, a laboratory study was carried out by [19] to assess the efficiency of slow sand filtration. The results showed that slow sand filtration with 0.43 mm particle sand size is highly effective at a filtration rate of 0.14 meter/hour. It removes around 91 % of turbidity, 89 % of suspended solids (SS), 77% of chemical oxygen demand (COD) and 85% of biochemical oxygen demand (BOD). Although that the authors have mad many layer iterations, they determined the optimum flow for each iteration. In [20], the authors were not fully satisfied of his results as the filtered water did meet the standard of drinking water. However, it is recommended to fill the filters with finer sand particles (0.2 to 0.45 mm), and the sand layer should not be less than 40 cm in order to see better results.

In terms of modeling approach, [21] proposed the first mathematical model in 1935 based on laboratory experiments. The filtration columns contained algae and white clay. The filtration coefficient was basically based on deposited material accumulates. In [22], the authors studied several pretreatment techniques applied for seawater reverse osmosis desalination process. They measure the silt density index (SDI) of the produced water in addition to other important parameters such as filtrate flux, trans membrane pressure, total suspended solids, colloidal silica, total organic carbon, etc. According to the quality produced sample by the conventional media-filtration technique the SDI varied from 2.8 to 3.6 which reflect a slight consistency as SDI should be less than 3.0.

In [23], the authors reviewed the early consideration history of slow sand filtration and presented a column designing method with a theoretical aspect. They discussed the advantages and disadvantages of slow filtration especially the simplicity of operation and the ability of the process to remove microorganisms from water. They tried to find out the techniques suit the pre-treatment water and the applicability in developing countries.

The size and uniformity coefficient of sand particles stay the major concerns for many researchers as explained before. Based on previous research findings, the most effective size for sand filtration is between 0.35 mm and 0.15 mm, while the best performance can be if the uniformity coefficient is less than 2 [24]. In [25], the authors have designed a Bio-Sand slow filter to treat water coming from wells, spring, river, and rainwater. Their filter

does not have any replaceable parts and can remove up to 90% of bacteria, 100% parasites, 50 to 90% of organic and inorganic toxins, 95 to 99% of zinc copper and lead and 47% of arsenic.

The climate class plays an important role in designing filtration unit. The unit can be built as an open system or as a closed box depending on surrounding conditions. For instance, cold humid climate requires a closed box because low temperature reduces process performance [10], while the arid climate requires an open system. In general application, a slow sand filtration consists a box often made of concrete placed a bed of sand on layer of gravel and ended by a pipes system to collect treated water. Recently, plastic boxes have been used as filter containers [26].

The major objectives of this research are to produce water for the specific purpose of agriculture consumption and encourage the use of -low cost-slow sand filtration technique in order to improve clean water availability for Al-Batinah region. The purpose of this research is to evaluate the filtration process under several media and layer properties.

2. Methods and setting experiment

Seawater in the world's oceans has a salinity average of about 3.5% (35 g/L, 599 mM) [27]. In general, seawater pH ranges between 7.5 and 8.4 [27, 28]. Seawater salinity is not uniformly distributed throughout the world, whereas, the majority of seawater has a salinity of between 31 g/kg and 38 g/kg [29]. The most dominant dissolved ions in seawater are sodium, chloride, magnesium, sulphate, and calcium [30]. The compositions of the total salt component are: Cl^- 55%, Na^+ 30.6%, SO_4^{2-} 7.7%, Mg^{2+} 3.7%, Ca^{2+} 1.2%, K^+ 1.1%, other 0.7% [31]. However, small amounts of other substances are found.

2.1. Seawater sampling

In November 2017, 19 grab samples of seawater from Sohar area, Gulf of Oman were collected at 5m to 20 m interval. Usually, the temperature in November is less than other months of the year; therefore, the evaporation rate is relatively less. Consequently, the sea water is slightly diluted.

The latitude and longitude were recorded in order to interpolate the parameter values in further steps. Figure 1 shows samples collection area in Sohar at Gulf Oman. However, an investigation presented by the Middle East Desalination Research Center (MEDRC) in Muscat, Sultanate of Oman indicated that seawater quality in the Gulf of Oman has significantly greater parameters values than other sites in the world [32] adding another challenge to the current research.

Figure 1: Seawater sampling area, Sohar, Gulf of Oman

2.2. Routine tests

Total suspended solids (TSS) test was conducted to determine the level of inorganic and organic substance contained in seawater before and after the filtration process. The lower level of TSS indicates purer water. The method of measuring TSS is based on evaporating sample of water and then weighting the residues (Figure 2). Nevertheless, TSS remains an important parameter to evaluate filtered water quality (examples [33–35]).

Figure 2: TSS test weighing procedure

In addition, pH and electric conductivity tests were conducted to measure how filtration process has affected the water quality. The conductive ions indicated the dissolved salts and inorganic materials such as alkalis, chlorides, and carbonate compounds are in higher concentration.

2.3. Design of Filters

There are different design dimensions of filter units ranging from 20 cm to 4 m based on the purpose of the research [36–38]. Three acrylic column filters with different layers components have been used. The height of each filter is 60 cm, while the width is 30 by 30 cm (Figure 3).

Figure 3: Designed filters

Adding a limestone layer to the filter unit will improve its efficiency in removing heavy metals, ammonium ions, and phosphates [39,40]. Therefore, limestone was collected from a near area called Wadi Hibi, west part of Sohar, and used as a layer among many others (Figure 4). The stone samples were crushed

using the Loss Angeles machine for 10 minutes to produce fine particles. Each sample contains 2000 g of limestone. Sieve analysis was used to assess particles size distribution. The size distribution is often of critical importance to the way the material performs in use. The limestone particles size was between 6.3 mm and 425 μ m.

Many researchers have placed coarsest gravel at the bottom while the a finest gravel and sand layers placed above [41,42] sand and gravel layers were collected, washed using distilled water, and particles size has been recorded which was between 9.5 mm and 425 μ m (Figure 5).

Figure 4: Limestone samples collection site used in the filtration units

Figure 5: Samples of gravel and sand layers

Furthermore, chlorophyll was extracted from the palm leaves (*Phoenix dactylifera*) a common tree in Oman. Palm leaves are having significant concentration of chlorophyll a and b [43]. Chlorophyll is known as the green substance responsible for the photosynthesis process. The photosynthesis process is strongly interconnected with pH values. The target from this step is to reduce the high values of seawater pH values by adding a layer of chlorophyll to produce glucose and oxygen from water and carbon dioxide. Rubber particles and activated carbon were used as separate two layers in the filtration process. In fact, those two layers have been used for several purification purposes: chemical, physical, and biological treatment [44,45]. Figure 6 shows the recycled rubber provided from Rubber-NEKTEL Company in Sohar Industrial Zone. This implementation might give an environmental concern.

Figure 6: Rubber particles

The pH is a major parameter of water quality evaluation. Most of cited research papers have conducted pH test before and after filtration processes. Additional pH test was made to evaluate how seawater is influenced by each material separately (Figure 7) under continuous mixing process for 24 hours.

Figure 7: individual pH test of each material

However, several iterations including present or absent of the materials, order of the layers, and thickness were evaluated. First filter contains 7 different layers, second filter contains 9 different layers, and third filter contains 12 different layers with different thickness. Tables 1 to 3 show details filter profiles according to their order, thickness, and types of material. The arrangement of layers are from up to down. The Freeboard is around 25 cm. Figure 8 shows a filter sample and materials setup.

Table 1: First filter layers order, types of material, and thickness

Layers order	Type of material	Thickness
1	Gravel	5 cm
2	Cotton	4 cm
3	Fine sand	5 cm
4	Cotton	2 cm
5	Carbon	5 cm
6	Chlorophyll	2 cm
7	Gravel	10 cm

Table 2: Second filter layers order, types of material, and thickness

Layers order	Type of Material	Thickness
1	Gravel	6 cm
2	Fine Limestone	2 cm
3	Powder calcium	2 cm
4	Chlorophyll	3 cm
5	Fine sand	6 cm
6	Shell	1 cm
7	Carbon	6 cm
8	Fine Limestone	2 cm
9	Gravel	8 cm

Table 3: Third filter layers order, types of material, and thickness

Layer order	Type of Material	Thickness
1	Gravel	9 cm
2	Textile	0.5
3	Fine calcium	3.5 cm
4	Textile	0.5
5	Rubber	5 cm
6	Textile	0.5
7	Fine sand	3.5 cm
8	Textile	0.5
9	Powder calcium	1.5 cm
10	Algae	1
11	Carbon	8 cm
12	Gravel	7.5 cm

The flow within each layer was tested using Darcy equation [46] which relates the head loss or pressure loss due to friction along a given profile length. The equation is suitable for an incompressible flow where water moves by gravity. The equation according to Darcy as following [47]:

$$Q = -KA \frac{dh}{dl}$$

where:

dh is the change of head loss due to layer friction over the given length of the profile

dl is the change of layers length

A is the cross-sectional wetted area (m²).

K is Darcy friction factor for each material used, the representative values were taken from [48].

To assess the relationships between different variables results Pearson correlation was used based on the following formula:

$$r = \frac{\sum(x - \bar{x})(y - \bar{y})}{\sqrt{(\sum(x - \bar{x})^2)(\sum(y - \bar{y})^2)}}$$

The values of Pearson correlation are always between -1 and 1, and if x and y are not related the correlation is equal to zero. The relationships between routine tests before and after were evaluated. Filter unit results with significant correlation reflect a weak purification process.

Figure 8: Filter sample and materials setup

3. Results and discussion

Due to a lower turbulation process, low rainfall rates, and higher evaporation rates in comparison to other parts of the world; the seawater in the Gulf of Oman has higher values of pH, conductivity and, TSS. Water Samples collected from seas near France, Korea, and Malaysia showed a significant lower value of those parameters [49].

The average pH value for the collected seawater samples was 9.17, conductivity was 12.97 mS/cm, and the total suspended solid (TSS) was 12.42 mg/L. Figures 9, 10, and 11 shows the spatial location and distribution values of conductivity, pH, and TSS respectively. All samples indicate that, seawater is a base solution because the pH is higher than 7. Even the sample were collected in a short distance interval (5 m), still one can recognize the differences between the samples. Overall, it is conspicuous that the pH values are higher in samples 12, 13, 14 and 15 which were equal to 9.3 while the lowest value of the pH was in sample number 1 (8.9). As mentioned by [50] a high pH value of seawater is connected to a high concentration of minerals such as Boron, Copper and Nickel.

Figure 9: the location of the 19 seawater samples and conductivity values in Ms/cm of the before filtration in the study area

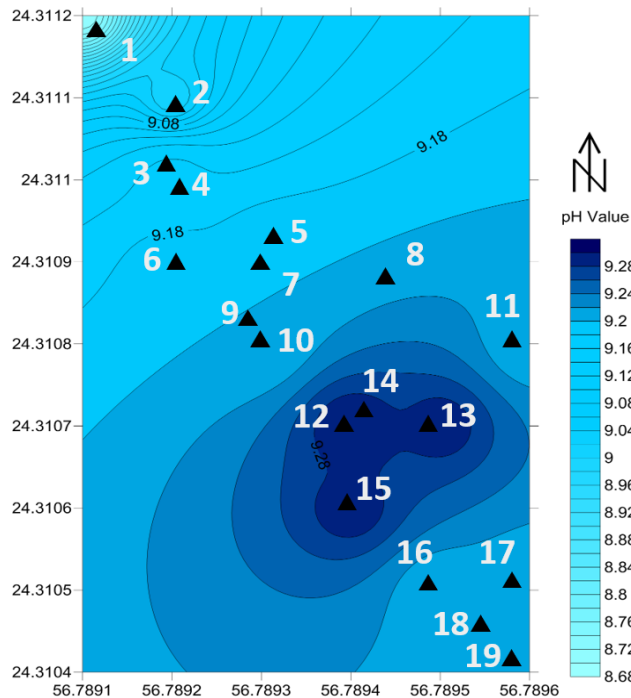

Figure 10: the pH values of the 19 seawater samples before filtration in the study area

In general seawater is a good conductor because of the presence of salts and impurities. Samples number 8 and 9 showed the highest conductivity values namely 13.12 Ms/cm which reflects a higher the concentration of solid minerals in those samples. With no significant drop; sample number 14 has the lowest conductivity value which was 12.85 Ms/cm. In this regards, [51] recommended the use ceramic microfiltration membrane to enhance sea water quality, while reverse osmosis unit remains the

efficient method to remove complex matrix of seawater minerals [49]. However, slow sand filtration has failed in reducing the conductivity into an acceptable level.

Figure 11: the TSS values in mg/L of the 19 seawater samples before filtration in the study area

In addition, the TSS tests of untreated samples showed that the values were between 0.2 mg/L and 50 mg/L for samples number 12 and 3 respectively. The three filters have showed very optimistic results in removing TSS, decreasing the value from 12.42 mg/L in average into less than 2.5 mg/L. Similarly, a technique proposed by [14] to use granular materials for dual-media filtration of seawater showed very matching results.

As per Pearson correlation, there is a significant correlation between pH and conductivity values for 19 samples. However, this was not the case for the correlation pH or conductivity values with TSS values which indicates a weak relationship (Table 4).

Table 4: Pearson correlations for measured parameters

		pH	Conductivity	TSS
pH	Pearson Correlation	1	0.989	.077
	N	19	19	16
Conductivity	Pearson Correlation	0.989	1	.364
	N	19	19	16
TSS	Pearson Correlation	0.077	0.364	1
	N	16	16	16

Typically, there are many alternatives to develop or add layer materials in order to improve filtered water quality. At a Nanoscale the pH test was conducted after individually mixing

seawater samples with each layer materials for 24 hours with seawater samples. This procedure helped to understand the level that each layer materials impact pH values. The results show that all materials reduced the pH from 9.17 to 8.9 (fine limestone), 8.4 (Mix of fine limestone and palms chlorophyll), and 7.8 (palms chlorophyll). Due to the photosynthesis reactions the levels of pH value has been reduced [52].

In a different approach, sieve analysis was conducted in this research to determine the particles size distribution of the selected filtration materials. It is an evident that sieve can be used to separate both fine and coarse aggregate into different particles size in order to select a proper K value for the flow using Darcy law. Based on Darcy law and flow records, filter three has the longest residence time and lower flow per time. However, the water residence time and flow rate is different from one filter to another because of material types and thickness. The fastest flow was in filter one with an average of 0.5 L/minutes, filter two has an average flow of 0.088L/minutes, while filter 3 has a flow rate of 0.026 L/minutes. Therefore, the water residence time in filter three is longest among all filters.

By introducing an average seawater sample into the three filters, the results showed that for the value of pH in all filters has been reduced. In more details, filter one has the lowest value of pH which reflects the reaction made by palm leaves chlorophyll and limestone in with oxygen worked to reduce the value of pH. On the other hand, the results of TSS showed alternative value and filter 3 has the lowest value in TSS.

The results of conductivity test for the first and second filters have indicated a slight increase while filter three has a reduced value of conductivity from 13.06 to 12.81 Ms/cm. In fact, filter three has more layers than the other two, a thicker activated carbon layer, and additional fine rubber layer. Unfortunately, the iterations of layers in filters one and two were not able to reduce the conductivity. Table 5 shows the comparison between routine tests before and after the filtration process for the three filters. There are two major reasons of having better results in filter three:

- Increasing the thickness and the number of limestone and activated carbon layers, this will increase water residence time which gives the chance to flow slower. However, increased flow rates in filter one and two have an adverse effect.
- Adding a rubber media has also brought decreased range of conductivity in filter three thus proving to be an upcoming new filter material.

However, the values of the three filters fall within the water quality standard required for agricultural activities as per water quality legalization report [53].

The methodology used for outlining seawater quality combines the advantages of implementing new materials in the filtration process with statistical reality. In fact, to support best decision, multiple performance criteria indicated that filter three can provide a better water quality as the reduction of pH, TSS, and conductivity was significant. However, highly appreciated designs require more iteration, deeper media layers, and more time to apply. Its challenging to have a proper water quality due to constraints of the experimental filter unit dimensions.

Table 5: pH, TSS, Conductivity comparison (before and after filtration)

	Before Filtration	After filtration			Water Quality Legislations*
		Filter 1	Filter 2	Filter 3	
pH	9.4	8.4	9	8.7	6.5-8.4
TSS (mg/L)	12.42	1.68 2	2.478	1.2 00	1.2-10
Conductivity Ms/cm	13.06	13.3 3	13.21	12. 81	<1302

*Oman Standard for unbottled Drinking Water [53].

Considering the current water scarcity in Oman, this paper is an additional effort to meet the expectation of Oman strategic plan and the vision of 2040. Cheap and easy techniques to produce and use the current state-of-the-art filtration materials are highly required.

4. Conclusion

This research has proposed a new method to improve water filtration, particularly, seawater. Generally, slow sand filter have a successful implantation in reducing pH, TSS, and conductivity of seawater samples. The use of natural material such as palms chlorophyll, and local limestone showed a great influence on filtration process. In addition, the use of the rubber which considered a major waste dilemma in developing countries is also improving the results of filter three. Although it's not the standard of drinking water, all routine test values including pH, and TSS in all filters have been decreased which can meet the agricultural needs. While conductivity test for filtered seawater showed only filter three has improved the quality in comparison to the other two filters.

Through this research, it has been recommended to increase the dimensions of filters to accommodate larger quantities of water during filtration process. In addition, Increase the number of layers used in each filter will give more accurate results.

Conflict of Interest

The author declares no conflict of interest.

ABSTRACT

In recent years water treatment methods under pressurized systems have been considered as the optimum high-rate filtration techniques. Unpressurized-slow sand filtration can be the cheapest and most efficient method, among others. This research aims to test the performance of a reliable seawater filtration system, using three different iterations. The filters have been designed considering many types of filtration layers such as sand, gravel, palm chlorophyll and other layers. The results of routine tests showed that the seawater pH, and TSS, and conductivity in the Gulf of Oman are relatively high. The pH values were decreased from 9.4 to 8.4 (filter 1), 9.0 (filter 2), and 8.7 (filter 3). Filter three has a reduced value of conductivity from 13.06 to 12.81 Ms/cm while a slight increase in filters 1 and 2. The TSS values were significantly reduced from 12.42 mg/L to 1.682 mg/L (filter 1), 2.478 mg/L (filter 2), and 1.200 mg/L (filter 3). This reflects the efficiency for each filter for this parameter is 86.5% for filter 1, 80% for filter 2, while 90.3% for filter three. Water velocity through each layer was monitored using Darcy law where the water of filter three has the longest residence time and slowest flow per time. The fastest flow was in filter one with an average of 0.5 L/minutes, filter two has an average flow of 0.088 L/minutes, while filter 3 has a flow rate of 0.026 L/minutes. The third filter has provided the best performance according to the results. Statistical analysis was conducted to understand the correlation between different parameters. As per Pearson correlation, there is a significant correlation between pH and conductivity values for 19 samples (0.989), while the correlation with TSS is relatively weak (0.364).

1. Introduction

Oman lies in an arid climatic strip where the fresh water is limited [1]. Most of desalination processes in the country based on pressurized systems which require huge amount of energy and cost. Many kinds of particles can be found in seawater such as organic materials, suspended and dissolved solid coupled with high turbulence. Slow sand filtration is a method used for hundreds of years to produce better quality water [2]. In general term, water purification is a process of removing pollutants from water mainly to produce water for human use while the process can also be extended for various other purposes including agricultural and industrial needs especially in regions where water resources are limited. Depending on the sources of raw water, particle removal can be accomplished through physical, chemical, and biological processes [2]. However, slow sand filtration used

mainly physical process such as sedimentation and adsorption starting by removing fine particles to some organic matters. Because of the slow flow rates within the filtration media, the raw water sits above the sand for several hours before passing through [3]. Slow sand techniques are considered to be an proper for small scale systems such as farms and houses since the operating procedure and maintenance are simple [4]. As slow sand filters are simple, efficient, and economic, they are appropriate methods of water treatment in developing countries [5]. The purification efficiency of water in slow filters is high where the rate of removal turbidity may reach 100%, bacteria removal ranges between 89% and 99% [6] while the removal of color of 20-30% and 60% iron compounds [7].

Biological process is essential in the slow sand filtration operation, which is based on fine sand particles ranging from 0.15 to 0.35 mm [8], a bed thickness of 0.8 to 0.9 meters [9]. In [10], the authors summarized the advantages of using slow-sand filters

*Corresponding Author: Eyad Abushandi, Civil Engineering Stream, Faculty of Engineering, Sohar University, 0096891273733, Email: eabushandi@gmail.com

in two major points: first, acceptable levels of treated water quality, and second, low cost and easy of construction. While the disadvantages of slow-sand filters were cited by [11]:

- Not efficient in filtering viruses
- No protection against chemicals, especially chlorine which may lead to recontamination
- Routine cleaning can damage the bio-layer and reduce efficiency
- Not easy to move the unit into another place due to the weight and initial cost of installation.

In addition, slow sand filtration treatment unit will occupy a large area of land and require more control tests on a regular basis, which means more labor is required during cleaning process. In some tropical climates, there is a risk algae grows which will proliferate in slow sand filters causing filter blocking, change water taste and odor [12]. Sand filters may consist different layers and depths of sand, gravel, and activated carbon. In fact, there are different hypotheses on the depth of each filter layer based on the efficiency and amount of water required. In some cases, the depth of the sand layer can reach 2.5 m, while in compressed units or compressed filters; the depth of sand layer is not more than 1.2 m and not less than 80cm for required efficiency [13].

In [14], the authors tested new granular materials for dual-media bed filtration of seawater and to assess the quality of the filtrate regarding criteria for feeding reverse osmosis desalination installations. Two different filter columns, one with the new materials namely clay and Mono Multi filter, and another filter with anthracite coal 1.2–2.5 mm on upper part of a sand layer 0.8–1.25 mm. However, both filters had similar performance in removing particulates and producing filtrates of acceptable quality. In fact, the authors studied the impact of relatively high or low temperature gradients simulating summer and winter conditions. A formation of larger aggregates occurred in the column where the temperature is higher, thus reducing the flow rate and hydrostatic head. While the impact of the materials physical properties played a key role, the authors concluded that the higher temperature (summer) campaigns performed better.

In [15], the authors investigated the nature of the biological accumulation in filters during the filtration process of North seawater. The biological accumulation of two different types of filters (coarse, 80 μm and fine 5 μm) was investigated over a 24-months duration. They assessed the seasonality effect, particularly; temperature during cold and hot seasons on the accumulation of both organic and inorganic materials showed that the filter life in hot seasons is shorter due to higher biological activities. The research of [16] was conducted to assess the viability of slow sand filter using dolochar to filter waste water from an industrial source. Efficiency of slow sand filters was assessed using two laboratory conditions. A dual media filter showed higher removal ability, particularly, average chemical oxygen demand removal of up to 80.96% compared to 64.68% of a single sand media filter, and turbidity removal of 91.13% compared to 82.27% of a single sand filter. In addition, the total suspended solids (TSS) removal efficiencies of sand and dolochar media filter 89.08%, while in the single sand media filter removal efficiency was 82.48%. The authors concluded that the dual media filter which includes a

biofilm layer has better performance in comparison with a single sand media. The performance of slow sand filters in removing bacteria was carried by [17]. They study the physical properties of the layers mainly the grain size distribution and grain shape intermittently. Bacteria removal was conducted using two different filter media namely Rhine sand-spherical shape and Lava sand-angular shape with three different particle size distributions. A better achievement was observed by the filter unit which included lava sand layer. This result reflects the effect of smaller grain size and an angular shape of sand grain lead which lead to an increase in bacteria removal.

The research carried by [18] demonstrated the ability of slow sand filtration as tertiary treatment operating with municipal wastewaters. At a laboratory scale the filtration process was capable to remove at least 90% of suspended solids, over 65 % of BOD, and more than 95 % of the bacteria. As per the study physical properties of the layers plays a major role in removing contaminants. In addition, a laboratory study was carried out by [19] to assess the efficiency of slow sand filtration. The results showed that slow sand filtration with 0.43 mm particle sand size is highly effective at a filtration rate of 0.14 meter/hour. It removes around 91 % of turbidity, 89 % of suspended solids (SS), 77% of chemical oxygen demand (COD) and 85% of biochemical oxygen demand (BOD). Although that the authors have mad many layer iterations, they determined the optimum flow for each iteration. In [20], the authors were not fully satisfied of his results as the filtered water did meet the standard of drinking water. However, it is recommended to fill the filters with finer sand particles (0.2 to 0.45 mm), and the sand layer should not be less than 40 cm in order to see better results.

In terms of modeling approach, [21] proposed the first mathematical model in 1935 based on laboratory experiments. The filtration columns contained algae and white clay. The filtration coefficient was basically based on deposited material accumulates. In [22], the authors studied several pretreatment techniques applied for seawater reverse osmosis desalination process. They measure the silt density index (SDI) of the produced water in addition to other important parameters such as filtrate flux, trans membrane pressure, total suspended solids, colloidal silica, total organic carbon, etc. According to the quality produced sample by the conventional media-filtration technique the SDI varied from 2.8 to 3.6 which reflect a slight consistency as SDI should be less than 3.0.

In [23], the authors reviewed the early consideration history of slow sand filtration and presented a column designing method with a theoretical aspect. They discussed the advantages and disadvantages of slow filtration especially the simplicity of operation and the ability of the process to remove microorganisms from water. They tried to find out the techniques suit the pre-treatment water and the applicability in developing countries.

The size and uniformity coefficient of sand particles stay the major concerns for many researchers as explained before. Based on previous research findings, the most effective size for sand filtration is between 0.35 mm and 0.15 mm, while the best performance can be if the uniformity coefficient is less than 2 [24]. In [25], the authors have designed a Bio-Sand slow filter to treat water coming from wells, spring, river, and rainwater. Their filter

does not have any replaceable parts and can remove up to 90% of bacteria, 100% parasites, 50 to 90% of organic and inorganic toxins, 95 to 99% of zinc copper and lead and 47% of arsenic.

The climate class plays an important role in designing filtration unit. The unit can be built as an open system or as a closed box depending on surrounding conditions. For instance, cold humid climate requires a closed box because low temperature reduces process performance [10], while the arid climate requires an open system. In general application, a slow sand filtration consists a box often made of concrete placed a bed of sand on layer of gravel and ended by a pipes system to collect treated water. Recently, plastic boxes have been used as filter containers [26].

The major objectives of this research are to produce water for the specific purpose of agriculture consumption and encourage the use of -low cost-slow sand filtration technique in order to improve clean water availability for Al-Batinah region. The purpose of this research is to evaluate the filtration process under several media and layer properties.

2. Methods and setting experiment

Seawater in the world's oceans has a salinity average of about 3.5% (35 g/L, 599 mM) [27]. In general, seawater pH ranges between 7.5 and 8.4 [27, 28]. Seawater salinity is not uniformly distributed throughout the world, whereas, the majority of seawater has a salinity of between 31 g/kg and 38 g/kg [29]. The most dominant dissolved ions in seawater are sodium, chloride, magnesium, sulphate, and calcium [30]. The compositions of the total salt component are: Cl^- 55%, Na^+ 30.6%, SO_4^{2-} 7.7%, Mg^{2+} 3.7%, Ca^{2+} 1.2%, K^+ 1.1%, other 0.7% [31]. However, small amounts of other substances are found.

2.1. Seawater sampling

In November 2017, 19 grab samples of seawater from Sohar area, Gulf of Oman were collected at 5m to 20 m interval. Usually, the temperature in November is less than other months of the year; therefore, the evaporation rate is relatively less. Consequently, the sea water is slightly diluted.

The latitude and longitude were recorded in order to interpolate the parameter values in further steps. Figure 1 shows samples collection area in Sohar at Gulf Oman. However, an investigation presented by the Middle East Desalination Research Center (MEDRC) in Muscat, Sultanate of Oman indicated that seawater quality in the Gulf of Oman has significantly greater parameters values than other sites in the world [32] adding another challenge to the current research.

Figure 1: Seawater sampling area, Sohar, Gulf of Oman

2.2. Routine tests

Total suspended solids (TSS) test was conducted to determine the level of inorganic and organic substance contained in seawater before and after the filtration process. The lower level of TSS indicates purer water. The method of measuring TSS is based on evaporating sample of water and then weighting the residues (Figure 2). Nevertheless, TSS remains an important parameter to evaluate filtered water quality (examples [33–35]).

Figure 2: TSS test weighing procedure

In addition, pH and electric conductivity tests were conducted to measure how filtration process has affected the water quality. The conductive ions indicated the dissolved salts and inorganic materials such as alkalis, chlorides, and carbonate compounds are in higher concentration.

2.3. Design of Filters

There are different design dimensions of filter units ranging from 20 cm to 4 m based on the purpose of the research [36–38]. Three acrylic column filters with different layers components have been used. The height of each filter is 60 cm, while the width is 30 by 30 cm (Figure 3).

Figure 3: Designed filters

Adding a limestone layer to the filter unit will improve its efficiency in removing heavy metals, ammonium ions, and phosphates [39,40]. Therefore, limestone was collected from a near area called Wadi Hibi, west part of Sohar, and used as a layer among many others (Figure 4). The stone samples were crushed

using the Loss Angeles machine for 10 minutes to produce fine particles. Each sample contains 2000 g of limestone. Sieve analysis was used to assess particles size distribution. The size distribution is often of critical importance to the way the material performs in use. The limestone particles size was between 6.3 mm and 425 μ m.

Many researchers have placed coarsest gravel at the bottom while the a finest gravel and sand layers placed above [41,42] sand and gravel layers were collected, washed using distilled water, and particles size has been recorded which was between 9.5 mm and 425 μ m (Figure 5).

Figure 4: Limestone samples collection site used in the filtration units

Figure 5: Samples of gravel and sand layers

Furthermore, chlorophyll was extracted from the palm leaves (*Phoenix dactylifera*) a common tree in Oman. Palm leaves are having significant concentration of chlorophyll a and b [43]. Chlorophyll is known as the green substance responsible for the photosynthesis process. The photosynthesis process is strongly interconnected with pH values. The target from this step is to reduce the high values of seawater pH values by adding a layer of chlorophyll to produce glucose and oxygen from water and carbon dioxide. Rubber particles and activated carbon were used as separate two layers in the filtration process. In fact, those two layers have been used for several purification purposes: chemical, physical, and biological treatment [44,45]. Figure 6 shows the recycled rubber provided from Rubber-NEKTEL Company in Sohar Industrial Zone. This implementation might give an environmental concern.

Figure 6: Rubber particles

The pH is a major parameter of water quality evaluation. Most of cited research papers have conducted pH test before and after filtration processes. Additional pH test was made to evaluate how seawater is influenced by each material separately (Figure 7) under continuous mixing process for 24 hours.

Figure 7: individual pH test of each material

However, several iterations including present or absent of the materials, order of the layers, and thickness were evaluated. First filter contains 7 different layers, second filter contains 9 different layers, and third filter contains 12 different layers with different thickness. Tables 1 to 3 show details filter profiles according to their order, thickness, and types of material. The arrangement of layers are from up to down. The Freeboard is around 25 cm. Figure 8 shows a filter sample and materials setup.

Table 1: First filter layers order, types of material, and thickness

Layers order	Type of material	Thickness
1	Gravel	5 cm
2	Cotton	4 cm
3	Fine sand	5 cm
4	Cotton	2 cm
5	Carbon	5 cm
6	Chlorophyll	2 cm
7	Gravel	10 cm

Table 2: Second filter layers order, types of material, and thickness

Layers order	Type of Material	Thickness
1	Gravel	6 cm
2	Fine Limestone	2 cm
3	Powder calcium	2 cm
4	Chlorophyll	3 cm
5	Fine sand	6 cm
6	Shell	1 cm
7	Carbon	6 cm
8	Fine Limestone	2 cm
9	Gravel	8 cm

Table 3: Third filter layers order, types of material, and thickness

Layer order	Type of Material	Thickness
1	Gravel	9 cm
2	Textile	0.5
3	Fine calcium	3.5 cm
4	Textile	0.5
5	Rubber	5 cm
6	Textile	0.5
7	Fine sand	3.5 cm
8	Textile	0.5
9	Powder calcium	1.5 cm
10	Algae	1
11	Carbon	8 cm
12	Gravel	7.5 cm

The flow within each layer was tested using Darcy equation [46] which relates the head loss or pressure loss due to friction along a given profile length. The equation is suitable for an incompressible flow where water moves by gravity. The equation according to Darcy as following [47]:

$$Q = -KA \frac{dh}{dl}$$

where:

dh is the change of head loss due to layer friction over the given length of the profile

dl is the change of layers length

A is the cross-sectional wetted area (m²).

K is Darcy friction factor for each material used, the representative values were taken from [48].

To assess the relationships between different variables results Pearson correlation was used based on the following formula:

$$r = \frac{\sum(x - \bar{x})(y - \bar{y})}{\sqrt{(\sum(x - \bar{x})^2)(\sum(y - \bar{y})^2)}}$$

The values of Pearson correlation are always between -1 and 1, and if x and y are not related the correlation is equal to zero. The relationships between routine tests before and after were evaluated. Filter unit results with significant correlation reflect a weak purification process.

Figure 8: Filter sample and materials setup

3. Results and discussion

Due to a lower turbulation process, low rainfall rates, and higher evaporation rates in comparison to other parts of the world; the seawater in the Gulf of Oman has higher values of pH, conductivity and, TSS. Water Samples collected from seas near France, Korea, and Malaysia showed a significant lower value of those parameters [49].

The average pH value for the collected seawater samples was 9.17, conductivity was 12.97 mS/cm, and the total suspended solid (TSS) was 12.42 mg/L. Figures 9, 10, and 11 shows the spatial location and distribution values of conductivity, pH, and TSS respectively. All samples indicate that, seawater is a base solution because the pH is higher than 7. Even the sample were collected in a short distance interval (5 m), still one can recognize the differences between the samples. Overall, it is conspicuous that the pH values are higher in samples 12, 13, 14 and 15 which were equal to 9.3 while the lowest value of the pH was in sample number 1 (8.9). As mentioned by [50] a high pH value of seawater is connected to a high concentration of minerals such as Boron, Copper and Nickel.

Figure 9: the location of the 19 seawater samples and conductivity values in Ms/cm of the before filtration in the study area

Figure 10: the pH values of the 19 seawater samples before filtration in the study area

In general seawater is a good conductor because of the presence of salts and impurities. Samples number 8 and 9 showed the highest conductivity values namely 13.12 Ms/cm which reflects a higher the concentration of solid minerals in those samples. With no significant drop; sample number 14 has the lowest conductivity value which was 12.85 Ms/cm. In this regards, [51] recommended the use ceramic microfiltration membrane to enhance sea water quality, while reverse osmosis unit remains the

efficient method to remove complex matrix of seawater minerals [49]. However, slow sand filtration has failed in reducing the conductivity into an acceptable level.

Figure 11: the TSS values in mg/L of the 19 seawater samples before filtration in the study area

In addition, the TSS tests of untreated samples showed that the values were between 0.2 mg/L and 50 mg/L for samples number 12 and 3 respectively. The three filters have showed very optimistic results in removing TSS, decreasing the value from 12.42 mg/L in average into less than 2.5 mg/L. Similarly, a technique proposed by [14] to use granular materials for dual-media filtration of seawater showed very matching results.

As per Pearson correlation, there is a significant correlation between pH and conductivity values for 19 samples. However, this was not the case for the correlation pH or conductivity values with TSS values which indicates a weak relationship (Table 4).

Table 4: Pearson correlations for measured parameters

		PH	Conductivity	TSS
pH	Pearson Correlation	1	0.989	.077
	N	19	19	16
Conductivity	Pearson Correlation	0.989	1	.364
	N	19	19	16
TSS	Pearson Correlation	0.077	0.364	1
	N	16	16	16

Typically, there are many alternatives to develop or add layer materials in order to improve filtered water quality. At a Nanoscale the pH test was conducted after individually mixing

seawater samples with each layer materials for 24 hours with seawater samples. This procedure helped to understand the level that each layer materials impact pH values. The results show that all materials reduced the pH from 9.17 to 8.9 (fine limestone), 8.4 (Mix of fine limestone and palms chlorophyll), and 7.8 (palms chlorophyll). Due to the photosynthesis reactions the levels of pH value has been reduced [52].

In a different approach, sieve analysis was conducted in this research to determine the particles size distribution of the selected filtration materials. It is an evident that sieve can be used to separate both fine and coarse aggregate into different particles size in order to select a proper K value for the flow using Darcy law. Based on Darcy law and flow records, filter three has the longest residence time and lower flow per time. However, the water residence time and flow rate is different from one filter to another because of material types and thickness. The fastest flow was in filter one with an average of 0.5 L/minutes, filter two has an average flow of 0.088L/minutes, while filter 3 has a flow rate of 0.026 L/minutes. Therefore, the water residence time in filter three is longest among all filters.

By introducing an average seawater sample into the three filters, the results showed that for the value of pH in all filters has been reduced. In more details, filter one has the lowest value of pH which reflects the reaction made by palm leaves chlorophyll and limestone in with oxygen worked to reduce the value of pH. On the other hand, the results of TSS showed alternative value and filter 3 has the lowest value in TSS.

The results of conductivity test for the first and second filters have indicated a slight increase while filter three has a reduced value of conductivity from 13.06 to 12.81 Ms/cm. In fact, filter three has more layers than the other two, a thicker activated carbon layer, and additional fine rubber layer. Unfortunately, the iterations of layers in filters one and two were not able to reduce the conductivity. Table 5 shows the comparison between routine tests before and after the filtration process for the three filters. There are two major reasons of having better results in filter three:

- Increasing the thickness and the number of limestone and activated carbon layers, this will increase water residence time which gives the chance to flow slower. However, increased flow rates in filter one and two have an adverse effect.
- Adding a rubber media has also brought decreased range of conductivity in filter three thus proving to be an upcoming new filter material.

However, the values of the three filters fall within the water quality standard required for agricultural activities as per water quality legalization report [53].

The methodology used for outlining seawater quality combines the advantages of implementing new materials in the filtration process with statistical reality. In fact, to support best decision, multiple performance criteria indicated that filter three can provide a better water quality as the reduction of pH, TSS, and conductivity was significant. However, highly appreciated designs require more iteration, deeper media layers, and more time to apply. Its challenging to have a proper water quality due to constraints of the experimental filter unit dimensions.

Table 5: pH, TSS, Conductivity comparison (before and after filtration)

	Before Filtration	After filtration			Water Quality Legislation ns*
		Filter 1	Filter 2	Filter 3	
pH	9.4	8.4	9	8.7	6.5-8.4
TSS (mg/L)	12.42	1.68 2	2.478	1.2 00	1.2-10
Conductivity Ms/cm	13.06	13.3 3	13.21	12. 81	<1302

*Oman Standard for unbottled Drinking Water [53].

Considering the current water scarcity in Oman, this paper is an additional effort to meet the expectation of Oman strategic plan and the vision of 2040. Cheap and easy techniques to produce and use the current state-of-the-art filtration materials are highly required.

4. Conclusion

This research has proposed a new method to improve water filtration, particularly, seawater. Generally, slow sand filter have a successful implantation in reducing pH, TSS, and conductivity of seawater samples. The use of natural material such as palms chlorophyll, and local limestone showed a great influence on filtration process. In addition, the use of the rubber which considered a major waste dilemma in developing countries is also improving the results of filter three. Although it's not the standard of drinking water, all routine test values including pH, and TSS in all filters have been decreased which can meet the agricultural needs. While conductivity test for filtered seawater showed only filter three has improved the quality in comparison to the other two filters.

Through this research, it has been recommended to increase the dimensions of filters to accommodate larger quantities of water during filtration process. In addition, Increase the number of layers used in each filter will give more accurate results.

Conflict of Interest

The author declares no conflict of interest.

ABSTRACT

The purpose of this study is to determine the improvement of the competence of junior high school students through the application of blended learning models. This is a Classroom Action Research comprising of two cycles and two observations of student activities, with the descriptive statistics used for data analysis. From the results of the learning process during the two cycles, it was found that students who learned using blended learning models obtained a better competency improvement in the second cycle. The results of the calculation from the first cycle showed that the average competence of students tested in English learning was 70.12 with an activity level of 65.5%. Furthermore, in the second cycle, the competence became 78.00 with an activity level of 70.23%.

1. Introduction

According to March (2020), students tend to be less active in exploring their English knowledge. Therefore, several studies have predicted using the blended learning model in schools to improve student learning outcomes in English. This model enables students to learn by interacting with Websites, Videos, or Learning E-Modules. This process was carried out at Junior High School Leuwigoong, Garut Region.

The rapid development of technology, communication, and information, especially the internet, has increased the need for Indonesian teachers to use it as a positive tool to support learning quality. Similarly, through e-learning, learning services become more flexible and can be carried out anywhere, irrespective of the time [1]. One positive value of Internet technology is that it allows students to discuss and collaborate to solve classroom problems and outside the school [2].

The concept of blended learning is a mixture of learning patterns. Blended learning is a combination of face-to-face and online learning to increase students' level of knowledge and analytical skills [3].

^{*}Corresponding Author: Deni Darmawan, Universitas Pendidikan Indonesia, Street of dr. Setiabudi, 229 Bandung, 40154, Phone +6222013163, Email: deni_darmawan@upi.edu

Several schools in Indonesia still use the traditional face-to-face learning process, irrespective of the rapid growth in information and communication technology (ICT). Online learning makes it easy for students to explore the knowledge and information needed in education [4]. Therefore, based on this phenomenon, this research aims to research questions on using the blended learning model to improve students' English competence at Junior High School Leuwigoong, Garut Regency.

2. Theoretical Review

2.1. Educational Technology

The current change in education from traditional to media communication using digital technology has significantly increased students' knowledge and skills. According to several educational experts such as [5]-[9], the face to face educational process between the teacher and students have changed due to the development of digital technologies [10].

However, students and teachers still find it difficult to master the technology, and therefore, various educational institutions in Indonesia are still using the traditional learning method. Therefore, it is hoped that educational institutions develop a learning revolution that turns face-to-face learning into a digital-based learning model. Educational Technology is a procedure used to solve student learning problems. In practice, it requires the

competence of teachers with technological literacy. Similarly, teachers need to possess the ability to carry out learning using various sources, such as textbooks, journals, magazines, newspapers, CD ROMs, videos, radio, television, websites, social media, blogs, etc [11]. Furthermore, online learning is achieved by developing applied research designed in the form of integration between technology, digital media logs, computer motherboards, and audio-video input-output connected to broadcast television programs via satellite captured by the TV. Toners are used to create media communication to monitor and obtain programming options with positive educational values and learning to provide e-Learning services to the community.

2.2. Online Learning

Online learning is a model that has been used to achieve knowledge by open universities in the United States and the United Kingdom since the mid-1960s. This process converts materials such as lectures and simulations into videotape forms, which are distributed using the internet, DVDs, and CDs, thereby making it easier for students and teachers to learn and explore knowledge [12]. However, students need to combine online and face-to-face learning, known as blended learning, to maximize knowledge. Research conducted by [13] stated that blended learning can improve student learning outcomes and increase their interest in education compared to using only online learning.

Online learning consists of media consisting of a controller which grants the user access. Meanwhile, offline media is not equipped with a controller because users do not need to be connected to the Internet network. Examples of offline materials are tutorials on CDs or media made through students' applications without connecting to the internet network [14]. According to Mayes and Marison in Jeffrey, many teachers are interested in online learning, while Bates and Sangra stated that online learning needs direct understanding to provide feedback between teachers and students [15].

Learning needs to be carried out by installing a healthy internet joint learning management system through effective technology in developing countries [16]. The purpose of the blended learning model is to obtain the best learning by revising the various advantages of each component of conventional methods and online features. Blended learning is carried out by combining online and face-to-face learning using print, audio, audiovisual, computer, and M-learning technologies (mobile learning). The blended learning method comprises of six things, namely face to face, independent learning, application, tutorial, collaboration, and evaluation. In more detail, the needs that can be freed from the blended learning process are (1) sending subject material through E-learning, in the form of files uploaded and downloaded by students, (2) procurement of quizzes with new methods, using timers, random questions, and automatic assessment, (3) giving online assignments, (4) ability to visualize students' grades online (5) discussion forums, (6) user-friendly displays, and (7) telecommunications technical sharing forums [17].

2.3. Blended Learning

Blended learning is the solution to online learning's weaknesses because it combines online, offline, and face-to-face

learning processes. Students need to adopt the right learning outcomes to understand the essential competencies of vocabulary mastery to enhance their learning outcomes. This educational model combines classical teaching (face to face) with online instruction. In [18], the author stated that Blended Learning is a logical evolution in knowledge acquisition. It provides solutions to the challenges of tailoring learning and development to individual needs. Furthermore, blended learning is an opportunity to integrate innovative advancements and technology offered by online learning with the best interaction and participation from the traditional process. Blended learning provides more flexibility in terms of time, place, and variety than online and face-to-face methods. Blended Learning's application encourages students to understand the material better and be more active in participating in educational activities to enhance their knowledge. This learning also emphasizes students to learn independently by utilizing various sources. Learners naturally build knowledge, which is applicable in their daily lives [19].

3. Research Method

The classroom action research method adopted from the [20] models were used to carry out this research. This study consists of 2 cycles, where each comprises four activities, namely planning, action, observation, and reflection. Therefore, the research process is deductive to answer the problem statement, a concept or theory is used. Furthermore, the research design was developed into three stages in the learning process. The addition of this stage is carried out to examine whether the blended learning model's application has the ability to affect student learning outcomes at each location.

This research was carried out in the even semester of the 2019/2020 school year of Junior High School Leuwigoong in Garut region, west java. The research subject consists of all students of grade VII of junior high school as the research samples.

Data were collected through observation, test, and interview methods. Learning activities with this Blended Learning strategy tend to continue to the next cycle assuming the indicators have not been successfully achieved. Furthermore, the obtained data were analyzed using descriptive statistics.

4. Result and Discussion

Online learning is also called distance learning that enables teachers/lecturers students to acquire knowledge outside school/college irrespective of their location. In this process, the teacher gives a tutorial and provides assignments to students to assess the subject matter's source on the internet. Therefore, based on the results of the classroom action research carried out, the English competence of students of junior high schools Leuwigoong at Garut Region is improved, as shown in Figure 1. The picture shows student competency scores in quantity from the increase in the pre-test and post-test scores. From these results, the findings were further confirmed by interview data and observations from peer teachers.

Figure 1 shows an increase in the learning outcome achieved by students from the pre-test and post-test achievements. These findings indicate that teachers' role of mobile learning, both in the first and second cycles, positively impacts student competence.

Figure 1: Implementation of Blended Learning

Therefore, the students' English competence was enhanced after the Figure 1 shows an increase in the learning outcome achieved by students from the pre-test and post-test achievements. These findings indicate that teachers' role of mobile learning, both in the first and second cycles, positively impacts student competence. Therefore, the students' English competence was enhanced after the implementation of two processes in the classroom. In [21], Blended learning combines face-to-face learning with the help of Information and Communication Technology ICT. Its advantages are as follows:

- Students interact directly with the content of learning.
- Enables users to interact with friends.
- Group discussions and exchange opinions,
- Access e-libraries, virtual classes.
- Online assessment.
- E-tuitions.
- Access and maintain learning blogs.
- Online seminars (webinars).
- Provide expert lecturers on youtube.
- Learn online via video and audio.
- Virtual laboratory.

Blended learning combines various educational tools such as real-time software, online web-based programs, and other applications not supporting the learning environment and knowledge management systems[22]. Blended learning combines online, face-to-face, and it is independently guided by mentors, teachers, or lecturers with structured education and its description.

Learning in this study is appropriate to support the curriculum and strategies in line with students' characteristics. Innovative work consists of teaching materials and the learning media that value innovation in schools. Teachers are expected to professionally use innovative work in learning to provide creative works obtainable from sources.

Such as the internet and store school supplies. The teacher also creates innovative work, which acts as a point and one of the requirements that need to be utilized.

This increase was due to the contribution of the use of Blended Learning in acquiring knowledge in English. This finding is in line with [23] research on how teachers teach in a balanced way, as reinforced by [24], which confirms that most

teachers used well-developed engagement strategies in classrooms compared to online.

5. Conclusion

In conclusion, the learning process used in this research was carried out using a video-based online blended learning process to introduce the material and assignments. The study results in the first cycle showed that the average score for the observation sheet of students' learning creativity is 65.5% and in the high category. By the end of the second cycle, the use of online learning video is still performed, with a percentage of 70.23% in the very high category. This shows that the Blended Learning Model positively influences student learning outcomes with an increase from cycle I to cycle II. The average value of daily tests led to 70.12 and 78.00 in the first and second cycles, respectively. There is an average value of daily difficulties and minimum completeness criteria in English subjects, especially in the essential competencies of vocabulary improvement.

Blended learning-based online learning videos are teaching materials used by teachers and students to acquire knowledge. Online learning videos are rated by teachers as interactive teaching materials because they contain text, images, videos, animations, interactive quizzes, and other interactive features that attract students' attention. It is also considered efficient by the teacher because it is easy for students to learn. Teachers are also interested in making and using online learning videos in education with enthusiasm to help students.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

The web documents are automatically interacting to discover the information by web mining, which is one of the applications of Cloud Computing (CC) technologies. These documents may be in the form of structured, semi-structured, or unstructured formats. In current web technologies, the Semantic Web is an extension for better enabling the people and computers to work together, where the information is well defined. Before storing the data to the cloud server, data owners should encrypt their data for privacy and security concerns. At the same time, the end-user, who is finding the data related to specific keywords, suggests the research on searchable encryption technique. In this research work, fine-grained authorization of search was achieved by developing the Attribute-Based Encryption (ABE) search technique, which is under the distribution of multiple attribute authorization. Finally, to validate this approach, an experimental study is conducted on Wikipedia as an ontology with existing techniques. This research applies the Attribute based encryption and search method for the effective search and improve security in the cloud. Access policy, cipher text and secret key is developed based on the Attribute selected from the data. The Lagrange interpolation method is applied for the search process and registration key is applied to access the data. The privacy preserving efficiency of the proposed model is 99.2 % and existing Hierarchical-ABE method has 96 % efficiency.

1. Introduction

In the past few years, the World Wide Web (WWW) is considered as one of the most important resources for knowledge discoveries and retrieval of useful information due to the vast amount of available online data [1, 2]. The process of retrieving the information from knowledge discovery by using web mining technologies is one of the right solutions on Web. The performance is improved for Web based data warehousing, web information retrievals and question answering by extracting the knowledge from the Web [3]. There is an availability of user's private sensitive data in web based databases because the web services are integrated into our daily life. These sensitive data of user can be accessed by unauthorized persons who are having malicious intentions and the reason behind this is the huge availability of web [4]. The requirements of the users should be matched with the privacy policies of service provider to reduce the disclosure of private data. According to the various policies such as privacy as

well as security, the service users' privacy sensitive data will be secured [5, 6]. CC offers benefits and more services to system software and hardware of data center over Internet [7].

According to the customer requirements, the inclusive platforms or apparatus are divided, then the software is delivered to end user. In addition to this, the communication and storage over internet are considered as some of the important services of CC. Also, three important protection issues namely accessibility, privacy and reliability can be tackled by the techniques of CC [8]. A rich amount of information can be generated by web service users, while the service providers' websites are browsed and accessed through social networking sites for posting the comments and reviews of products by end user, then their data are stored in the cloud [9]. The new threats for digital life of user's privacy are raised due to increases in online activities of user and technologies [10]. The service users signed to the privacy policy of providers unknowingly for providing the authorization to them for collecting and sharing the personal identification information of user while accessing the web services [11]. When accepting the policies of providers, some users thought that they secured their privacy

*Corresponding Author: Rubin Thottupurathu Jose, Email: rubinthottupuram@gmail.com

information, but their rights are surrendered to the providers [12, 13]. This research work aims to reduce the disclosure of privacy related information by using prevalent semantic web based technologies. There are two major contributions of this work such as encrypt the collected data using ABE technique to preserve the users' access rights to the data. Then, the Attribute-based Search (ABS) scheme is developed on encrypted cloud data to support multiple users and multiple data owners. In order to reduce the search space of documents, the second index are exploited by cloud server during the process of search and the user can able to access these documents. Then, the relevant documents are retrieved by using the first index and these two methods are used as an effective and secure access control policy, where the data owner can outsource the encrypted data and retrieves the secure documents over the cloud. The proposed ABE search technique properties are as follows:

- This research involves in applying the fine-grained authorization with Attribute based Encryption and search algorithm method for effective search and improve security. The Attribute is used to develop cipher text and secret key for the user. Access policy are developed based on cipher text to control access over the data.
- The Lagrange interpolation method is used for the search process and registration key is used to access the data and Two index is used in this method for effective search and reduce the computational time for the authorization.

The proposed ABE search technique is compared with existing models in encryption and search process to analysis the performance. The performance evaluation is carried out for various parameters such as precision, recall, auditing time etc. The result shows that the proposed model has higher efficiency of 99.2 % and existing HABE method has 96 % efficiency shows lower auditing time compared to existing method.

The rest of the paper consists of a survey of recent techniques which is used to retrieve the encrypted data in semantic web mining are described in Section 2. The proposed techniques for preserving the users' access rights are presented in Section 3. The validation of the proposed method with existing techniques in terms of various metrics are represented in Section 4. Finally, the conclusion of this research work with further development is discussed in Section 5.

2. Literature Review

In this section, a review of recent techniques namely encryption techniques, access control solution and disclosure discovery methods based on privacy-preservation of end user tare presented in [14-20].

In [14], the author implemented a Hierarchical-ABE (HABE) based modular padding scheme to address the challenges in public auditing. The semantic ontology was generated by assigning the key parameters to various data levels. The public auditing was carried out by this generated ontology, then the method verified the types of the user request and modular padding was performed. The efficiency of data sharing and quality of public auditing was improved by the HABE method. In case of system failure, the retrieval of user data was not concentrated by this HABE method.

In [15], the author developed a Three-Fold Sanitization (TFS) framework for detecting the sensitive topic semantically. The Gibbs Sampling was used to recognize the sensitive topic clusters with high location entropy, which was subjected to Semantic Sensitive Access Rule-LDA Topic Model (SSAR-LDA). The sensitive terms were eliminated by enhancing the privacy preserving policy of TFS, which replaced that terms with appropriate hierarchical generalization terms. The method faced the problem of language ambiguity, which leads to poor performance in detecting user profiles.

In [16], the author implemented the ontology-based access control solution to overcome the problem of interoperable exchange of security policies and stealing authentication credentials. According to the estimated trust degree of user's request and criticality of data resources, the method encompassed a risk-aware authentication scheme to overcome the vulnerabilities of malicious activities. The method used the pseudonyms by developing the privacy-preserving authentication and reputation management which was used to avoid the exposing personal information of users. The method failed to focus on possible issues such as data sovereignty for providing privacy and security guarantees in cloud computing.

In [17], the author addressed the inefficiency of technical knowledge and rigidity of access control mechanism, a transparent and dynamic Privacy-Driven Access Control (PDAC) was developed for textual messages. According to the privacy requirements of publishers, the sensitive information was detected by assessing the semantics of messages automatically. There is no need for administrative efforts at the publication time because privacy enforcement was transparent both to publishers and readers. The semantic coherence of the protected messages was affected by improperly disambiguated terms, which was considered as the main limitation of this approach.

In [18], the author prevented the illegal disclosure of user's sensitive privacy information by developing a Private Data Chain Disclosure Discovery (PCDD) method. The cost and similarity degree of disclosure of private data were measured, then key private data and disclosure chain were detected based on the measurement of private data (i.e. cost and similarity degree). When user released the private data to other software services, the disclosure of user's sensitive private data was identified in time by using this approach. In the description tree, when there was a presence of huge quantity of un-matching nodes, then the time efficiency of this algorithm was very high.

In [19], the author proposed a Secure Inverted Index (SII) using homomorphic encryption and dummy documents technique to solve the privacy issues of end user. Even though, the two techniques had limitations, this approach obtained benefits from these two methods by using compressed table of encrypted scores and double score formula. The user's access rights to data were managed by using second secure inverted index. After encrypting the index documents, the eight dummy documents were added to test the search time of secure inverted index technique.

In [20], the author implemented an Index Hash Table (IHT) with Paillier Encryption (PE) for dynamic public auditing by recording the data property that was located at TPA. The information were migrated to TPA from CSP for the reduction of

computation cost and communication overhead. The privacy preservation was supported by combining the random masking with homomorphic authenticator, which was based on public key. When compared with previous scheme, the DHT method reduced the storage costs, communication and computation cost by achieving secured auditing in clouds.

In [21], the author developed a key-insulated ciphertext policy ABE with key exposure accountability (KI-CPABE-KEA) for providing protection of KE and achieving the user accountability. The ciphertext was decrypted by data receiver, when the self-centric policy was matched with the attributes of data receiver. Every private key of user had unique identifier, so system manager pinpointed the user's identity, if the private key was exposed for illegal data sharing. The security analysis showed that the KI-CPABE-KEA had higher efficiency for sharing the data in CC. However, the developed method was insufficient for data authentication in attribute based cryptosystem.

In [22], the author solved the issues of revealing the encryption's privacy by implementing the CP-ABE scheme. The encryptor's and decryptor's privacy policy was preserved by adding the hidden access policy with CP-ABE scheme. Before decryption process, the unnecessary operations were avoided and solved the efficiency issues by introducing the testing phase in the CP-ABE scheme. While comparing with decryption computation, the testing phase's computation cost was minimized and this developed scheme was secure under chosen-plaintext attack. According to AND gates with wildcards on multi-valued attributes, the access policy of the scheme was highly expressive and it was affected by decisional bilinear Diffie-Hellman (DBDH) attack.

In [23], the author protected the data confidentiality, while sharing the data over cloud by developing the CP-ABE with fine-grained access control. Under the standard mode, the assumption of DBDH was minimized by the security of the developed scheme. The security analysis showed that the developed scheme has higher efficiency and protected the user's privacy. The validation was conducted by using the parameters such as storage cost and computation cost. But, the developed CP-ABE scheme was only used for securing the data.

The existing techniques are implemented to secure only the encrypted data and failed to effectively retrieve the document. An objective of the research is to address the issues of sensitive information from the attributes such as HIV, Christianity, Berlin, Exact, Plugin, Subsume, Homosexuality, leakage of user data and to improve the efficiency in privacy preservation. According to the nature of the sensitive topics, the requirements are considered for the protection which will focus on protecting the sensitive data such as HIV (sensitive disease) Homosexuality (sexuality) and in order to protect against the attribute disclosure in identifying data (locations, name of the person) will be protected against identity disclosures. Similarly, Christianity includes sensitive information (religion, Belief etc.), Berlin includes the Census data related with (location name or the city name) that are also protected against the identity disclosure.

The research work implements the ABE-based search algorithm for retrieving the related documents with higher accuracy.

3. Proposed Methodology

The sensitive information should be preserved for protecting the privacy of the end user. There may be a presence of contradictions in semantic web mining like extracting the useful information from the collected data without compromising the privacy of clients. While maintaining the usability of data, the privacy of sensitive data are preserved by developing various techniques namely differential policy, data perturbation and anonymization. But, the sensitive information are not mined from the given data context. Therefore, this information should be marked manually by data administrator, which is time consuming and tedious process. To address the issue, this research work implements the attribute based encryption and search algorithm (i.e. ABE and ABS) to preserve the privacy information of end users. In this section, a system model, threat model with design goals of proposed method are explained as below.

3.1. System Model

The system model for proposed ABE-based search technique is shown in Figure 1, which consists of four entities namely cloud server, data owner, administration server or Third Party Auditor (TPA) and data user. A set of files are encrypted and then uploaded to the cloud server by data owners. According to files and keywords, a secure searchable index is constructed by data owner using efficient ABE-based search technique and then these searchable indexes are submitted to the TPA by owner.

Suppose, a new user wants to search, initially he/she should register on the TPA server for searching the keyword of the data that is stored in the cloud. The user can able to send the authenticate attribute request to trusted authorities called Certificate Authorities (CA) by using legal identity, once the registration is successfully finished. The major function of CA is to verify the request and if the process of authentication is successful, then CA can provide the attribute key to end user. The encrypted trapdoor with searchable keyword can be generated by end user, when the keys are provided to them. The TPA re-encrypts the user's trapdoor with searchable keyword by using his secret keys. Then, TPA should submit the obtained index and trapdoor to the cloud server. While receiving the index and trapdoor, the server verifies the access control structure that belongs to the attributes of user's trapdoor. If the verification is successful, the cloud server returns the relevant cipher text by searching the encrypted index. The threat models are discussed below.

3.2. Threat Models

There is various important search scheme designed over the encrypted data using the threat model are discussed in this section.

Content Protection: Before outsourcing, the contents includes queries, indexes, and documents to cloud. The user should encrypt all these data.

Secure the Keyword: The frequency distribution and inter-distribution of a document are used by the proposed method to secure the data by hiding the information from the server. For every given document, the frequency distribution of a given term is described by term distribution and the distribution of term score

Figure 1: System Model of Proposed Method

is represented by inter-distribution. The links between documents and terms are prevented from the server by hiding these two features.

Trapdoor Unlinkability: The relationship between the collection of encrypted queries are gathered to prevent the information from the server, which can be carried out by proposed scheme. Therefore, there should be a non-deterministic of cryptosystem should be used.

Pattern Accessing: During the search, the proposed scheme should hide the sequence of resultant data from the server, while sending the data to user.

3.3. Proposed Methodology of Attribute Based Encryption Technique

Wikipedia is defined as ontology in this research work for exploring the meaning of documents and queries during the search process. There are more than four million English pages present in this ontology representation, where this research work chooses the Wikipedia due to its rich representation of information. Moreover, the articles in most languages and areas are presents in this ontology and the set of concepts are mapped between the concepts and terms, which are represented by query and document. In Attribute-based encryption, the ciphertext and secret key of a user depends on the attributes, where decryption process is carried out only when the attributes of ciphertext is matched with the user key. In this research study, the access policy are applied by data owner to control the access over the data collection by using ciphertext-policy ABE technique. During the encryption process, an access structure are defined for constructing the every data which will be included in the cipher text and the user's private key are presents in a set of attributes. If the access policy of the data are satisfied by the private key attributes, then the cipher text can be decrypt at the time of decryption process. Suppose, if it is not satisfied, then the user's private key will not able to decrypt the cipher text and also does not have the rights to access the data. The Table 1 shows the notation of parameters that are used in the research study.

Table 1: Parameter Notations

Notations	Definitions
MsK	Master Key
PuK	Public Key
At	Set of Attributes
PrK	Private Key
M	Number of Messages
As	Access Structure
Prk'	Set of New Private Key
A't	Set of New attribute set
CT	Cipher Text
K	Number of documents
Rki	Registration Key

There are five algorithms presents in this encryption method, which includes setup the process, generating the key, encrypt the data, decrypt and then delegate the data over the collected data. In the below section, these five algorithmic steps are discussed as:

- $Setup() \rightarrow \{Puk, MsK\}$: A two keys such as master key, which are represented as MsK and public key as Puk are generated by using this algorithm.
- $KeyGen(MsK, At) \rightarrow PrK$: This algorithm gives the input for encryption process by using two inputs, which includes a set of attributes At and MsK . Moreover, the private key for users as PrK are generated by using this algorithm, where these keys are generated only for authorized users who are related to the attributes set At .
- $Enc(PuK, m, AS) \rightarrow CT$. A message m is encrypted by using a public key PuK under an Access Structure As in this algorithm, which are executed by the data owner.
- $Delegate(PrK, A't) \rightarrow PrK'$. This algorithm uses the two kinds of inputs, which includes attributes set as $A't$ and a private key as PrK . A $A't$ is included in At because a private key of user is related with a set of attributes At . A new

private key as $Pr K'$ are developed by this algorithm that is the main aim of delegate, where this new private keys are associated with the set of attributes $A't$.

- $Dec(Pr K, CT, PuK) \rightarrow m$. A cipher text CT are decrypted by user, where this algorithm is used to execute this process. An access structure As are presents in the cipher text CT , which are taken as an input by this algorithm. In addition, the public key PuK and a set of attributes At are also presents in the user's private key $Pr K$. In order to get back the original message m , the cipher text CT should be decrypted, when the access structure As are satisfied by the set of attributes At .

The user's privacy information are preserved from the unauthorized access by using this encrypted data from the ABE technique. Then, cloud server will obtain the secure indexes and collection of encrypted data. A set of public keys are constructed by data owner, where trapdoors are built by these keys and finally the documents are decrypted by using private keys. The users who are authorized to the data, will receive these keys. A query is formulated by user to perform the search over the encrypted data using a public keys, which is used to build the trapdoor and these are send to the cloud server. The relevant documents are retrieved by using the search index, while the cloud receives the trapdoor function and then, authorized users obtained the $top-k$ documents. At last, the trusted authority will decrypt, filter and sorted the returned results at the user side. The next section will explain the ABS technique which is used to retrieve the documents for end user.

3.4. Proposed Method of Attribute Based Search Technique

An ABE technique encrypted the keywords and files of various data owners, and then the encrypted data are stored in the cloud server. Moreover, the secret data can be stored by administration server as TPA on this cloud server. Once the query request of user are received, all these data owners' files are searched by cloud server and then recalculate the Lagrange interpolation [24] (i.e. $LR = e(RK_i, g_2)^\beta$, where RK_i is the registration key. The cloud processes the search request in two steps such as initialization process and retrieval process.

Initialization Process: i) Compute whether the encrypted index of first index with secret key should be equal as the encrypted index of second index with other secret key and justify the values of Lagrange interpolation. ii) When the cloud server obtains the trapdoor and searchable index, the user should compute encrypted trapdoor with his secret key. If the condition satisfies, the top-k documents can be retrieved from the cloud and delivers to the user.

Retrieval Process: The encrypted documents are searched by using specific keywords, which are explained in this phase are as follows:

- Initially, the trapdoor function are called by creating the encrypted query, where this process can be done by an authorized user. Upon receiving the trapdoor, the cloud utilizes the first index to retrieve the relevant documents, and

simultaneously it exploits the second index to get the list of documents IDs that the user has the right to access.

- The document IDs with their encrypted indexes are returned to user by launching the search function, when the encrypted queries are received by server.
- At last, the Sort function is used to filter and sort the returned documents in the user side. Then, the selected concepts are sorted with regard to their first index then based on their second index in the case of equality. Finally, the top concepts with their associated index are used to represent the document as a sort function

During the search process, the cloud server exploits to reduce the search space to documents accessible by the user and uses the key words to retrieve the relevant documents. Once the data retrieved from the database based on the query given by the end-user, the user need to verify whether it is relevant to the query or not. The next section will be described the validation of proposed method with other existing techniques.

Algorithm for the proposed ABE search technique

G_1, G_2 are bilinear group of order $(p - \text{prime})$, ($g - \text{generator group}$) G_1

$G_1 \times G_2 \rightarrow G_2$ is bilinear mapping d being the threshold value

Generate the public key and master key by randomly selecting the trusted center t_1, \dots, t_n

y from finite field Z_q calculates the public key $P_k = (T_1 = g^{t_1}, \dots, T_n = g^{t_n})$

Generate Master Key $M_k = (t_1, \dots, t_n, y)$

Generate private keys $D = \{D_i = g^{(q(i)/t_i)}\} \forall i \in AU$

Encrypt the message encrypted using set of attributes A_{CT} from $M \in G_2$ using a set of attributes A_{CT} and a random number $s \in Z_q$

$CT = (A_{CT}, E = MY^s = e(g, g)^{ys}, \{E_i = g^{t_i s}\} \forall i \in AU$

The encrypted data are supplied to the input of the decryption algorithm, and the output of the algorithm is obtained decrypted message.

If $|A_U \cap A_{CT}| \geq d$

Select d attributes

Compute the first and second index

Compute sort function

Searchable encryption is completed with security.

4. Result and Discussion

In this section, the implementation of the proposed method using tools are briefly described and the experimental validation of these approach with other existing techniques along with the results are evaluated and discussed.

4.1. Parameter Evaluation

The experiments are implemented using Python 3.7.3 on a computer with Intel Core i5 CPU 2.2 GHz with 8.00 GB RAM. In

this experimental analysis, the performance of ABE-based search technique is validated by using various parameters such as precision, recall, searching time and privacy preserving efficiency. In this research study, two objectives are considered, where the performance of two objectives needs to validate with various metrics. Here, the retrieval performance is validated by using precision and recall. The proposed ABE-based search technique is compared with existing techniques namely HABE [14], TFS [15], PDAC [17], PCDD [18] and SII [19], which are explained in below section.

Precision: Among the detected sensitive data nodes, precision predicts the correct number of sensitive data nodes. The mathematical expression for precision can be given in Eq. (1):

$$\text{Precision} = \frac{TP}{TP + FP} \quad (1)$$

where, TP represented as True Positive, FP represented as False Positive.

Recall: While calculating the total number of detected sensitive data nodes, recall gives the percentage of correctly identified sensitive data nodes, which is explained in Eq. (2):

$$\text{Recall} = \frac{TP}{TP + FN} \quad (2)$$

where, FN is described as False Negative.

4.2. Security Analysis

To analyze the security aspect of the proposed ABE scheme, the security analysis are examined whether the security controls that are presented in subsection 3.2 are respected. In addition, the security of the encrypted reverse index and the access rights of users are examined.

i) Protected content: This control encrypts data such as indexes, collected data and queries that passes through the cloud server. Initially, ABE technique is used to encrypt the data scores used in this approach, where identifiers is described as documents and concepts. A set of concepts with associated weights are illustrated as trapdoor. Then, ABE technique is used to encrypt the every weight and every concept, which are described by an identifier. The contents of documents are encrypted by the proposed method and enables to apply an access control policy. In conclusion, the developed approach respects the control of protected content because the indexes, databases and queries are encrypted.

ii) Privacy keyword: This restriction is to prevent the server from establishing a link between the terms and the documents. Two properties such as term distribution and inter-distribution are used for this purpose that must be hidden. On the one hand, the distribution of the term scores in a given document are presented by inter-distribution. This property is hidden by ABE technique, which enables encryption of scores in the reverse index. On the other hand, each document in the collection contains the frequency of a given word, which is presented by term distribution. This property is hidden by the dummy document technique, which prevents the server from knowing if a word belongs to the documents leading to the corresponding entry. From this, it is

concluded that keyword privacy control is respected in developed approach.

iii) Trapdoor Unlinkability: This restriction is to prevent the server from linking between various trapdoors. For this purpose, the concepts (x) are selected at random from the set of ideas (y) that represent the query, for example, 10 x among the 100 y ideas is selected that represent the query. An ID is used to illustrate the each idea and ABE is used to encrypt its weights. This construction allows researchers to obtain various trapdoors for the same query. Therefore, the developed approach provides an undetermined encryption scheme, which allows to control the trap unlink ability.

iv) Access pattern: This restriction involves hiding user results from the server. While searching, a set of dummy document identifiers will always be provided with the correct result. The correct results are hidden from the server by using this false positives. In addition, developed technology allows the user to access the required documents without revealing their identities, which prevents the server from identifying false positives in the search result. Therefore, access pattern control is respected in this proposed approach.

4.3. Performance Evaluation of Proposed ABE Method

In this section, the validation of proposed ABE-based search technique is compared with PDAC [17] and PCDD [18] in terms of precision and recall. From the Wikipedia Ontology, this method chooses some sample sentences namely HIV, Christianity, Berlin, Exact, Plugin, Subsume, Homosexuality are used for validation. The ABE-based search method finds the access levels for sample sentences such as Infection and condition for HIV, religion and belief for Christianity, Location and City for Berlin, process and sexual activity for Homosexuality and so on. The security metrics involved in the proposed model are the privacy preservation efficiency, Verification time, auditing time and searching time. Table 2 shows the effectiveness of ABE-based search technique with existing techniques over precision and recall for sample sentences.

Table 2: Comparative Analysis of Proposed ABE-based search technique

Ontology Samples	Methodology					
	PDAC [17]		PCDD [18]		Proposed ABE-based search technique	
	Precision (%)	Recall (%)	Precision (%)	Recall (%)	Precision (%)	Recall (%)
HIV	66	77.77	65	63	80	87
Christianity	60	90	69	70	76	95
Berlin	75	80	73	59	84	86
Homosexuality	66	80	60	63	79	88
Exact	50	75	78	59	87	81
Plugin	57	71	73	63	91	79
Subsume	55	80	68	75	73.7	85.9

The above table explains the performance of proposed ABE-based search technique for precision and recall. The validated results stated that the proposed ABE shows better performance than PDAC and PCDD. The graphical representation for precision and recall is shown in Figure 2.

Figure 2: Performance of proposed ABE-based search technique

The existing technique PCDD achieved very low precision and recall for some samples such as HIV, Homosexuality, Berlin due to presence of noises and outliers in the Wikipedia ontology. These methods did not consider the user's access rights which leads poor performance in both precision and recall. The existing technique PDAC achieved higher precision and recall values, when compared with PCDD for all sample data. However, the disambiguated terms affect the semantic coherence of the protected message, which leads to low precision values in three samples namely exact, plugin and subsume (i.e. 50%, 57% and 55% precision). In this proposed method, the user access rights are preserved and also increases the semantic coherence of these messages by using ABS technique. Therefore, the validated results of ABE achieved nearly 80% in both precision and recall for all ontology samples. Table 3 shows the searching time of proposed method with existing techniques for retrieving the related documents using keywords.

Table 3: Searching Time of Proposed ABE-search based Technique

Methodology	Number of Queries							
	2	4	6	10	15	20	25	30
HABE [14]	24	29	34	40	51	57	64	70
TFS [15]	25	34	45	55	68	59	61	67
PCDD [18]	23	29	32	49	55	60	64	69
SII [19]	20	27	29	38	42	47	52	60
Proposed ABE-search based technique	18	23	26	31	39	44	49	54

The above table provides the searching time results in seconds for various number of queries. The searching time of proposed ABE is compared with various existing techniques namely HABE [14], TFS [15], PCDD [18] and SII [19] and their validated results are presented in the graphical structure, which is shown in Figure 3.

Figure 3: Searching Time of Proposed Method

Figure 3 shows that the proposed ABE-based search technique searches the queries in less number of time. When the sequential queries sizes increases, the searching time also increases. The existing techniques achieved nearly 70sec for 30th queries, but the proposed ABE method searches the sequential 30th queries in 54sec. Due to insufficient storage space, the existing techniques took larger time for searching the queries. The proposed ABE method overcomes the above issues by using index values. From the Table 2 and Figure 3 shows that the proposed ABE-based search technique performs better than existing techniques namely HABE, TFS, PCDD and SII. Table 4 shows the efficiency of privacy preserving of proposed method with various existing techniques, which was proposed in [14].

Table 4: Efficiency in Privacy Preservation of Proposed Technique

Methods	Efficiency (%)
Diffie Hellman	75
One-step	86
Multi-user inference	92
HABE	96
Proposed ABE-based search Technique	99.2

Figure 4: Efficiency of Privacy Preservation over Proposed Method

The experimental analysis of proposed method and their validated results are compared with various techniques, which is shown in Figure 4. The efficiency is used to calculate the privacy preservation of proposed ABE technique, which is stated in Table 4.

The existing techniques such as Diffie Hellman and one-step achieved very less efficiency (i.e. 75% and 86% privacy preservation in efficiency) when compared with other techniques. But, the HABE and Multi-user inference techniques achieved 96% and 92% efficiency due to padding process in the final step. The HABE method predicted the padding details from the ontology to generate the strings, then it adds more number of binary data to the end, which lead to time complexity and data loss from the server end. But, the proposed ABE-based search technique generates the strings when the encryption process takes place and stores the data in cloud. The proposed method avoids the data loss and preserved the privacy information of end user, which leads to achieve 99.2% efficiency. From the above experimental analysis of various parameters, the results stated that proposed ABE-based search technique achieved better results, when compared with existing techniques.

The experiments also evaluate the performance of ABE-based search technique in the verification scenario and compare it with DAP and Index Hash Table (IHT) with PE [20]. The verification time of the different block size is measured for the existing and proposed method, as shown in the Table 5 and Figure 5.

Table 5: Verification Time of ABE technique

Block Size (kB)	IHT - PA	DAP	ABE-based search technique
10	2.24	1.68	1.52
20	2.25	1.69	1.42
30	2.27	1.71	1.61
50	2.28	1.71	1.49
70	2.28	1.71	1.31
100	2.32	1.71	1.44
150	2.34	1.72	1.24
200	2.37	1.73	1.25

Figure 5: Verification of ABE-based search technique for different block size

The proposed ABE-based search technique has the lower verification time compared to the other existing method. The verification time of the DAP and ABE-based search technique methods has the much lower computational time than IHT-PA due to the significantly outweigh the disadvantage include by searching operation. When compared with other existing techniques, the proposed method achieved 1.25 sec for Block size 200. The experiments also evaluate the performance of ABE-based search technique in the batch auditing scenario and compare it with DAP and IHT-PE. The experimental results are as shown in Table 6 and Figure. 6.

Table 6: Auditing Time of Proposed Method

Block size(kB)	IHT - PA	DAP	ABE-based search technique
10	1.95	1.81	1.06
20	1.92	1.79	0.99
30	1.86	1.76	1.15
40	1.83	1.75	1.17
50	1.79	1.7	1.29
60	1.76	1.69	1.24
70	1.72	1.66	1.22
80	1.73	1.64	1.27
90	1.75	1.67	1.36
100	1.76	1.69	1.34

Figure 6: Auditing Time of Proposed Method

From the experimental results, it is clearly understood that the auditing time of proposed method is highly minimized with the existing techniques: IHT-PA and DAP. For instance, the proposed method nearly reduced the auditing time from 35%-40% for all files. In addition, the experimental results suggested that the batch auditing handle the verifications from multiple-users simultaneously. While performing the individual auditing for multiple times, this ABE-based search technique reduces the computational costs of TPA. Also, the results proved that the batch auditing protocol in ABE-based search technique is more efficient than that in DAP, and IHT-PA. The ABE-based search technique has lower computation time compared to the other existing method. The security of the method is increased by using

the secure key generation method. Hence, the proposed method can be applicable to practical use in the cloud auditing system.

5. Conclusion

The sensitive information of end user is secured in this research work by developing the attribute-based keyword search technique. Without knowing the true value of trapdoor and index, the cloud server performed the search with secure, which is ensured by constructing the secure ABE-based search technique. The proposed technique helped the numerous data owner for encrypting the data with various keys. The searching performance is improved and makes the process more natural by using the proposed ABE technique, where search request is completed by registered users without using the data owner's key. The trapdoor is generated, when the secret key is obtained by user from the CAs once the registration process is successful. The data are transmitted to cloud by user, where these data are encrypted by using re-encryption technique of management server, which will used to generate the trapdoor. The experiments are carried out on Wikipedia ontology to validate the performance of proposed ABE-based search technique in terms of various parameters such as precision, recall, searching time and efficiency in privacy preservation. When compared with existing techniques namely HABE, TFS, SII and so on, the proposed technique achieved higher recall (85.9%), precision (73.7%) and 99.2% privacy preservation efficiency with less searching time. However, the retrieval performance include precision is low, due to the length of the data. In future work, the length of the encrypted data can be reduced to increase the retrieval time of the searching keyword.

Student's Learning Perception

Clustering

Readiness

ABSTRACT

*This study has two objectives: to determine the level of readiness of first-year undergraduate students at the Universitas Indonesia (UI) and to investigate student's perception of MPKT (Integrated Character Development course) lecturers' readiness to manage online learning class. Proportional cluster sampling was applied, and 1466 freshmen from thirteen faculties participated. Data clustering and imputation of missing values were utilized to analysis the data. Clustering based on gender, faculty, previous e-learning experience ** were applied. The study shows that students perceived themselves as being ready to learn in an e-learning environment except Computer Science students who have been more exposed to e-learning and implemented online collaborative learning. Most students agree that MPKT lecturers are able to teach well except those of the Faculty of Computer Science, Faculty of Pharmacy, and Faculty of Social and Political Sciences who think that the teaching ability of lecturers need to be improved. Recommendations and future research topics are proposed based on the study results and in-depth interviews with some experienced online lecturers.*

1. Introduction

The progress of e-learning systems is influenced by advances in information and communication technology. The advantages of e-learning for learners include increased accessibility to information, better content delivery, personalized instruction, content standardization, accountability, on-demand availability, self-pacing, interactivity, confidence, and increased convenience [1].

E-learning has moved from several generations. The first generation in the range 1994-1999 used e-learning by re-assembling offline teaching material to online teaching material format. The development of the second generation from 2000 to around 2003 was supported by better internet access so that the idea emerged to create a virtual learning environment. The third generation (to date) the development of e-learning systems is characterized by massive collaboration and socialization learning environment, project-based learning, and reflective practices such

as creating e-portfolio accounts, tutorial repositories in learning in the form of blogs and program code repositories that allow people to implement theories from teaching material. The third generation is also affected by the massive use of mobile applications [1]. Research on e-learning covers a broad discussion. Not only research in terms of information systems such as student perceptions [1] and the success factors of e-learning development [2], but the development of e-learning system employs machine learning methods [3]. Classification and clustering methods can be further used to explore insights based on student learning experiences. The results of processing machine learning methods can be reported to the university or faculty to improve the quality of teaching services.

E-learning is defined as an approach to teaching and learning, representing all or part of the educational model applied, that is based on the use of electronic media and devices as tools for improving access to training, communication and interaction and that facilitates the adoption of new ways of understanding and developing learning [4]. E-learning is a choice of learning

*Corresponding Author: Titin Siswantining, Email: titin@sci.ui.ac.id

environment system where face-to-face activities (in learning activities) cannot be carried out either due to space and time limitations or force majeure events such as the covid19 pandemic that is now being faced. Learning activities at the university have now focused on the method of distance learning by implementing an e-learning system [5]. UI has implemented an e-learning management system (emas 1). Subjects, assignments, and discussions related to each subject based on collaborative learning have been implemented in emas [6]. Apart from the superiority of the emas features, each student has a different level of readiness in learning to use e-learning systems and we are also interested in knowing each student's perceptions of readiness in learning online. This study aims to investigate freshmen' (first semester student) readiness for e-learning, and their perception to the MPKT class in terms of the lecturers' readiness and the suitability of the syllabi. The main contribution of this study is grouping the level of readiness of students obtained from the e-learning readiness questionnaire adapted from [7] using clustering algorithm. Due to the adapted questionnaires is not published yet, and the original one was developed by other authors. We respect the privacy of student personal information so we remove the attributes of student personal information from the data we share. In addition, only those who signed the inform consent letter are included as respondents of the current study. The contribution of this research are:

- Grouping the level of readiness of students obtained from the e-learning readiness questionnaire using a clustering algorithm.
- We are sharing e-learning readiness questionnaire data and responses from each student for further research.
- We are also to answer these three research questions as an additional contribution as follows:
- What is the level of readiness of first-year students to study in an e-Learning environment?
- How is the suitability of the learning process of MPKT with the syllabus?
- What is the students' perception of MPKT lecturer's readiness to teach online?

2. Literature Study

2.1. E-learning Critical Success Factor and Variables

There are several studies that discuss the critical success factor (CSF) for e-learning. Research conducted by [8] states that an individual's experience in using computers is positively associated with higher learning performance using e-learning. Both intrinsic motivation [9] and extrinsic motivation [10] play an important role both for teachers and students in using e-learning systems. Research conducted by [11] classifies CSF into four main factors:

- Student observation for instructor characteristics (teaching style, bringing attitude to students, technology control, etc).
- Student characteristics (motivation, content perception, collaboration, etc).
- Ease of use of technology (easy access to e-learning systems, internet speed, etc).

- Institutional support (technical support, availability of teaching materials, etc).

CSF that has been mentioned is deepened into a perception of students' readiness for learning where this perception is influenced by several variables. Research by [12] shows that age, gender, previous experience of computers, technology acceptance, and individual learning styles as the most influential factors in technology acceptance by students because students need to transition from learning conditions, require face-to-face activities to learning conditions using e-learning.

Although the third generation is the readiest generation to use e-learning, that does not mean everyone shares the same experience. Based on this, we compiled a questionnaire adapted from [7], [13] consisting of three main components:

- Management of the environment in learning activities using the e-learning system.
- Interaction with course materials.
- Interaction with the e-learning community.

The participants of the study are first year students enrolled in the Matakuliah Pengembangan Kepribadian Terintegrasi (MPKT) course (Integrated Character Development Course), a compulsory course offered at the first semester.

2.2. Clustering

Clustering is one of the most common exploratory data analysis techniques used to get an intuition about the structure of the data. A cluster refers to a collection of data points aggregated together because of certain similarities. It can be defined as the task of identifying subgroups in the data such that data points in the same subgroup (cluster) are very similar while data points in different clusters are very different. In other words, the clustering algorithm tries to find homogeneous subgroups within the data such that data points in each cluster are as similar as possible according to a similarity measure such as euclidean-based distance or correlation-based distance [14]. The decision of which similarity measure to use is application-specific. Unlike supervised learning, clustering is considered an unsupervised learning method since there is no supplied ground truth from the data which is known as the target variable in supervised learning. Further inspection allows only data structure investigation based on data points grouping into definitive subgroups (clusters) [15].

2.2.1. K-Means Clustering

K-means is one of the clustering algorithms, a simple partitioning clustering algorithm that tries to discover K non-overlapping clusters where K is the number of assigned cluster. These clusters contain centroid (a cluster centroid is typically the mean of the points in that cluster). If there are K clusters (Student Readiness to Manage Online Class Cluster), there will be also K centroids [16], [17]. According to Figure 1, the K-means Clustering algorithm can be summarized as the following steps [18] :

- Determine the number of desired clusters.
- Establish the centroid coordinate.
- Determine the distance of each observation to the centroid.
- Group the observation according to the minimum distance.

Suppose $D = x_1, \dots, x_n$ is the data set to be clustered. K-means can be expressed by an objective function that depends on the proximities of the data points to the cluster centroids as given on equation 1.

$$\min_{\{m_k\}, 1 \leq k \leq K} \sum_{k=1}^K \sum_{x \in C_k} \pi_x \text{dist}(x, m_k) \quad (1)$$

According to equation 1 [16] :

- π_x stand as the weight of x .

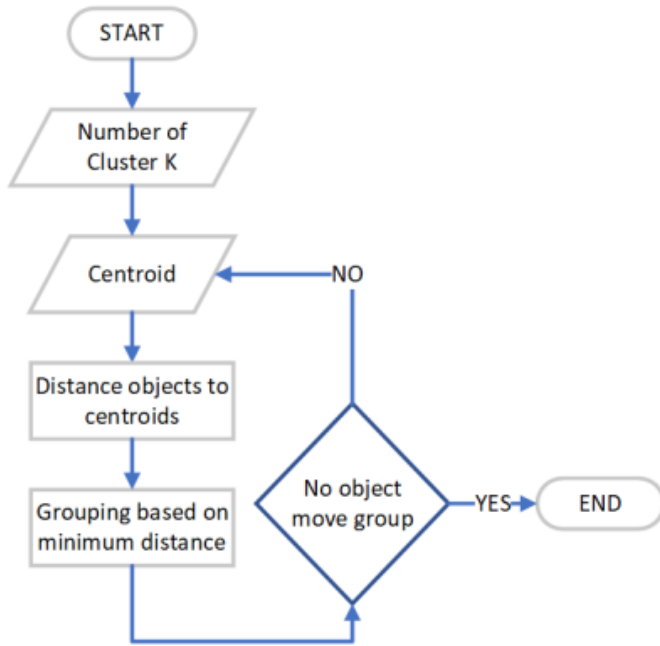

Figure 1: K-Means Clustering Algorithm

- n_k is the number of observation assigned to cluster C_k
- $m_k = \sum_{x \in C_k} \frac{\pi_x x}{n_k}$ is the centroid of cluster C_k . The number of centroid, matches the K provided by user.
- K is the cluster number. Note that this K value is set by user.
- The function dist aim to calculate distance between observation x and centroid m_k where $1 \leq k \leq K$.

Based on Figure 1, iteration can stop when there are no observations that move to another cluster. However, this method can lead to an infinite loop because there is at least one observation that is constantly moving clusters. In addition to the above conditions, one may add a limit (specifying iteration counter) to the number of iterations allowed in the k-means algorithm. Depending on which conditions are found first to stop the loop.

2.2.2. Cluster Number Evaluation

Evaluation of the number of clusters aims to find the number of clusters that are considered optimal for the k-means clustering algorithm, given the K value in the k-means clustering algorithm is determined by the user. This research employs elbow methods to evaluate the cluster numbers.

$$SSE = \sum_{K=1}^K \sum_{x_i \in S_k} \|x_i - C_k\|^2 \quad (2)$$

The idea of elbow methods is to compute variance between each data within each cluster towards the cluster mean. There's a point at which the clusters are at an optimum that point after which adding more clusters will not make a huge difference to the final number of clusters [19].

The k-means clustering algorithm will run for a range of values of K and each value of K calculates the sum of squared errors (SSE) using equation 2. According to equation 2, K is the current cluster counter, x_i is the current observation, C_k is the cluster mean and S_k stands for current cluster. In other words, $x_i \in S_k$ means the specific observation within cluster S_k . The loop carried on until the total number of cluster counter (K) is reached [20]. The maximum error value is found when the number of clusters is equal to 1 (all observations inside one big cluster). This happens because each observation has a difference that is not equal to zero to the average value of the cluster. The minimum error value is found when the number of clusters is equal to the number of observations because the distance of one observation to the cluster average value is zero. Observations using the elbow method are classified as subjective observations. One cannot directly define curves that are steep enough so that the number of clusters is said to be optimal.

2.3. Standardization

Standardization is the process of putting different variables on the same scale. This process allows us to compare scores between different types of variables. Standardizing tends to make the training process well behaved because the numerical condition of the optimization problems is improved. For example, suppose we have two-dimensional data that scatter around the first quadrant of the cartesian coordinate. Then we compute the mean value of the data. We then subtract the datum value with the mean value. After we have done those steps, the data will move towards (0,0) coordinate, providing better visualization, and reduce the variability of the data [21].

2.3.1. Z-Score

The standardization method used in this research is the z-score. Further explanation is depicted using equation 3. A z-score indicates how many standard deviations an element is from the mean [22]. According to equation 3, the Z variable is the data. After processed using equation 3, the data will have a mean score equal to zero and a standard deviation equal to 1. Note that x_i is the currently processing datum, μ is the mean score of the data (we have to calculate the mean score first) as given at equation 4 and σ is the standard deviation of the given data (we also have to calculate the data standard deviation first) as given at equation 5.

$$Z = \frac{x - \mu}{\sigma} \quad (3)$$

$$\mu = \frac{1}{N} \sum_{i=1}^N (x_i) \quad (4)$$

$$\sigma = \sqrt{\frac{1}{N} \sum_{i=1}^N (x_i - \mu)^2} \quad (5)$$

The z-score method is applied to every attribute in the dataset except for the identity attributes because we argue that cluster analysis conducted on the identity attribute occurs based on the cluster results obtained. The clustering stage in this study aims to create a response group given by participants regardless of the

identity of the participant. The k-means algorithm works by comparing the similarity of the attributes of each observation to the centroid of each cluster, the more similar the value of observation to a cluster, then the observations are considered as members of the cluster.

3. Methodology

3.1. Data Proportion and Initial Observation

3.1.1. Questionnaire Data

The questionnaire distributed to participants consisted of four parts:

- Participant's identity (given at Table 1).
- Managing the e-learning environment (given at Table 2).
- Interaction with teaching material (given at Table 3).
- Interaction with e-learning communities (given at Table 4).

Table 1: Participants Identity

No.	Questions
1.	Gender
2.	Senior High School Origin
3.	Admission Path
4.	Faculty
5.	Faculty Priority
6.	Online Learning Experience
7.	City of Origin
8.	Province of Origin

Table 2: Managing E-Learning Environment

No.	Questions
1.	Upload and download information and learning resources.
2.	Use search engines effectively.
3.	Skillfully use a web-browser to achieve learning goals.
4.	Utilize various software applications to improve learning outcomes.
5.	Using technology to help understand new things.
6.	Study in a disciplined and scheduled manner.
7.	Adjust to the online learning environment.
8.	Using technology to support the learning process.
9.	Identify the things needed to complete the task.
10.	Search for information on the internet intelligently.
11.	Take advantage that exist in online discussion forums.
12.	Make use of the online learning system.
13.	Work on assignments independently.
14.	Implement a problem-solving strategy.
15.	Scale priorities for tasks that must be completed at the same time.
16.	Utilizing feedback for self-evaluation.
17.	Choose the appropriate technology to complete the task.
18.	Solve problems that arise in the use of computers.
19.	Design task completion strategies.
20.	Look at yourself positively as a learner.
21.	Balancing learning commitments, social life, and family.
22.	Take advantage of discretion in the online learning environment.
23.	Conduct a process of reflection (self-assessing).
24.	Assess the process and self-learning strategy.

Referring to table 1, the Admission path is the UI entry point taken by each participant. The available admission path options are:

- **SNMPTN.** This admission path is known as the invitation path, considering the beginning of this reception based on invitations sent to schools. With the high enthusiasm of the school and students taking part in the acceptance based on report card grades, the invitation path has developed. In the Regular S1 (bachelor), the Ministry of Education and Culture through the Institute for Higher Education Entrance Tests (LTMPPT) opens the opportunity for all national curriculum schools to follow this path with the terms and conditions stipulated in an activity called the National Higher Education Entrance Test (SNMPTN). The use of the invitations admission path was cancelled because schools that have national school principal number (NPSN) and meet the SNMPTN requirements allowed to fill out the data without the need to get an invitation.
- **SBMPTN.** Students who do not meet the requirements to register for academic achievement through the SNMPTN admission path can register in the written examination path (SBMPTN). Restrictions on the year of graduating from senior high school/equivalent only apply to S1 Regular (maximum 3 years) and S1 International Class (5 years). Whereas the parallel Vocational and S1 Programs receive senior high school/equivalent alumni without limitation of the senior high school/equivalent year of graduation.
- **PPKB.** Universitas Indonesia Learning Opportunities and Equitable Learning Opportunities or so-called PPKB UI are new admissions paths based on academic achievement by students while studying in their schools (senior high school/equivalent). PPKB admission path is used before the SNMPTN period.
- **Talent Scouting.** Report card selection for the Vocational Program and the Parallel S1 Program is called the Achievement and Equal Learning Opportunities program, while the selection report card for the S1 International Class is Talent Scouting.
- **SIMAK.** UI Entrance Selection (SIMAK UI) is an integrated UI entrance examination held by UI for prospective students who wish to study at UI. Educational programs opened at SIMAK UI start from the Vocational Program (D3), Regular Bachelor, Parallel Class, Extension / Parallel Bachelor for D3 graduates, Professionals, Specialists, Masters, and Doctors.

Table 3: Interaction with Teaching Material

No.	Questions
1.	Linking initial knowledge with newly learned knowledge.
2.	Determine relevant teaching material.
3.	Learning teaching material in various formats (video, audio, images)
4.	Read and write according to learning needs.
5.	Take the essence of various information file formats (video, audio, images).
6.	Compare various sources to test the accuracy of information.
7.	Access information from various sources.
8.	Able to distinguish between relevant information and what is not.
9.	Evaluate information search results critically.

10. Be aware of understanding gaps.
11. Mixing various learning resources for sharing knowledge.
12. Use other sources of information (not limited to online communities or available technology).
13. Assessing websites related to teaching materials.
14. MPKT learning is carried out following Learning Reference Unit (SAP).
15. The task and learning task load of MPKT is following semester credit (SKS).

Table 4: Interaction with E-Learning Communities

No.	Questions
1.	Respect other participants when responding to opinions.
2.	Looking for information both independently and with the help of others.
3.	Always apply internet ethics.
4.	Communicate with others in online classes.
5.	Consider and appreciate feedback from other participants.
6.	Share personal experiences that are relevant to the topic.
7.	Collaborate to understand the lesson.
8.	Open to criticism.
9.	Appreciate the role of the lecturer as a learning facilitator.
10.	Contribute by proposing new ideas in discussions.
11.	Provide responses that are clear, precise, and unambiguous (multi-interpretation).
12.	See themselves as part of the learning community.
13.	Ask for clarification on the wrong understanding.
14.	Encourage others to respond.
15.	Explain opinions about a problem.
16.	Determine when the right time to listen or give a response.
17.	Manage time for regular online classes.
18.	Understand that the lecturer's response is a contribution and not a final decision in dealing with a problem.
19.	Providing constructive criticism of other people's responses.
20.	Begin interaction with other members of the learning community.
21.	Provide comments on the responses given by the lecturer.
22.	MPKT lecturers facilitate online learning well.

Faculty is the name of the current participant faculty. The priority of the faculty is the order of the faculties when participants register as UI students because one student may choose majors from different faculties when registering.

The participants are expected to use the following rules when answering the questionnaire:

- The entries for the senior high school origin, city of origin, and the province of origin sections follow the entries on the participant's identification card.
- Filling the faculty, faculty priority follows the choices available (containing the names of all faculties in the UI).
- The admission path response is done by crossing out unnecessary answers (SNMPTN, SBMPTN, PPKB, SIMAK, and Talent Scouting).
- Gender selection (male or female) and online learning experience (yes or no) is done by selecting one of the answers provided.
- The participants should give a number ranging from 0 to 10 for all of the remaining questions (given in Table 2, 3, and 4).

In the discussion of data preprocessing and clustering Table 2 will be mentioned as category A, Table 3 as category B, and Table 4 as category C.

3.2. Admission Competition

Figure 2 is a visualization of entering a faculty at UI for all study programs. We add up all registrants received at one faculty

against the number of registrants received at the same faculty. The equation used to get the graph in Figure 2 is given in equation 6. Based on equation 6, ap is the admission percentage, ar is the number of accepted registrants and r is the number of registrants. According to Figure 2, the smaller the percentage of student admissions to UI, the more difficult it is to enter a study program at the faculty and vice versa.

Figure 2: UI Admission Competition Level

The faculties that have the lowest level of competition are FIK (Faculty of Nursing) for all paths (SNMPTN, SBMPTN, SIMAK) and the faculties that have the highest competition are the FARMASI (Faculty of Pharmacy) and FASILKOM (Faculty of Computer Science). This study also reviews the perspective of clustering results from ranking the level of competition to be accepted as a UI student.

$$ap = \frac{ar}{r} * 100\% \quad (6)$$

3.3. Data Preprocessing

Data preprocessing aims to see the initial conditions of the data. The treatment of data includes:

- The number of initial observations by faculty. The number of observations in each faculty, the clusters formed tend to lead to the value of observation attributes in one particular faculty.
- Invalid imputation value is defined as the value that is filled out by participants outside of the predetermined rules including incorrect filling format and filling values outside the specified range.
- The presence of missing value. Observation that contain missing values cannot be further processed because it is assumed the participant already knows that each statement of the questionnaire must be filled with an appropriate response value.

Missing Values

The number of initial observations (rows) we received from the data is equal to 2081 observations. Figure 3 represents missing values for all attributes. In figure 5, JK is the attribute "gender", "Pengalaman" which is "online learning experience" and the "Jalur" is the "admission path" attribute. Figure 3 is the sum of missing values for all attributes. The attribute "Gender" (JK) contributes the most to the missing value, which is 28.5% or 377 observations from 1325 missing value (cell) events. 1325 these events spread over 614 observations (rows). We decided not to fill in the missing value because the forms filled out by the participants

were in the form of a questionnaire because there was no guarantee that the values filled with the missing value imputation method were the values that the participants wanted to fill.

Figure 3: Missing Values of All Attributes

Figure 4: Missing Values of Category A

Figure 5: Missing Values of Category B

The visualization of other attributes can also be seen in Figure 3. However, we realize that for a deeper look, Figure 3 is too simple. Missing value occurrences within category A, category B, and category C are given in Figure 4, 5, and 6, respectively. According to the distribution of missing values in categories A, B, and C, category C gives the most missing values, reaching 309 observations. In category C, attributes C_{16} , C_{17} , and C_{21} contributed the largest missing values, each with 21 observations. A description of these attributes is given in Table 5.

Figure 6: Missing Values of Category C

Table 5: Online Learning Experience Answer Distribution

Description	Attributes
Determine when the right time to listen or give a response.	C_{16}
Manage time for regular online classes.	C_{17}
Provide comments on the responses given by the lecturer.	C_{21}

Based on Table 5, the attributes of C_{16} and C_{17} are related to time management. We considered that participants had difficulty in managing time for attributes C_{16} and C_{17} . In C_{16} , we assumed that it was easier to learn by listening (preparing notes and focus on lecturers' explanations) than by listening and giving responses within a certain time. Participants who do not understand or are just learning a concept in a particular lecture will tend to prefer to listen and record all the information available in order to playback the recording later (outside teaching and learning activities). Organizing online classes regularly as stated in attribute C_{17} is not easy for participants. We assume that this is because the time to attend online classes is not from participants but from lecturers. The unavailability of choices we assume is the participant's motive in giving a null value to the C_{17} attribute. The interaction carried out by participants is asking questions and receiving answers from lecturers. Most of the answers from lecturers were recorded by participants for further study material. Attribute C_{21} asks participants' responses to comment on the lecturers' responses. This interaction is not a participant's habit so we assume it is the reason for the participant to give a blank value to attribute C_{21} .

Observations containing missing values are removed from the data. The number of observations which originally numbered 2081 observations reduced to 1467 observations.

3.4. Outliers

The conditions for filling out the questionnaire are:

- Imputation value must be a member of the real number domain.
- Participants only permitted to fill the questionnaire answer with a value ranging from 0 to 10.

We define outliers as events where values are found outside the fill range given in observation. Figure 6 illustrates the maximum value of each given attribute. The range of values that should be filled out by participants is 0 to 10. However, according to Figure 7, there are participants who fill in the value outside permitted range. Figure 7 depicts the maximum value imputed by participants. Figure 8 illustrates the number of observations that give outlier values based on attributes.

Table 6: Online Learning Experience Answer Distribution

Description	Attributes
Make use of online learning system	A_{12}
Linking initial knowledge with newly learned knowledge	A_{12}
Assessing websites related to teaching materials	A_{12}

Figure 7: Maximum Value on Each Attribute

Figure 8: Outliers Percentage on Each Attribute

Based on Figure 7, attributes A12, B1, and B3 get the biggest outlier response value among other attributes. Based on Table 2, we did not find an association between attributes. Instead of normalizing outliers, we choose to delete those attribute values because we don't have a solid reason to find a substitute value for outliers. To make it clear, suppose that we performed division by 10 to all outliers (a value bigger than 10), then we can only keep the performance up to 100, whereas there exist observations that score 120 on one of the questionnaires attributes so that the final value will still reaching 12 (permitted value ranges from 0 to 10). At this stage, the number of observations is equal to 1441 observations. The number of observations, marked as the end of the process of removing observations that contain outliers.

3.4.1. Invalid Imputation

After removing outliers, further exploratory data analysis was taken. In this stage, we are looking for invalid imputation. We defined invalid imputation as occurrences of value imputation to answer the questionnaire which violence the permitted format. If an entry is found that does not meet these conditions in one observation then the observation is considered invalid. Although the wrong imputation is given to only one attribute, we argue that attributes containing invalid imputation values are replaced with

an empty value so that one observer is eliminated from the data (note that our treatment of missing values also erases one observation where there is a missing value). Explicit list of invalid imputation done by participants is given in Table 7.

Table 7: Invalid Imputation

ID	Description
110	7,5,
119	-
119	-
119	-
108	8,,5
146	9*,5
111	-
905	.8.5

Table 7 lists participants who provided invalid imputation. Invalid imputations cannot be processed further because the data types provided are not numeric. For example, participants with ID 110 include "7.5," as an answer. The representation of the answer is incomprehensible because "7.5," is not considered a decimal number. If the answer given is "7.5", we will include the answer for further processing. Another example, participants with ID 119, three times include the answer "-". Then the answer representation also cannot be processed further because it violates the terms of writing the answer. We do not provide options that allow participants to leave the answers blank. Instead of leaving the answers blank, we allow participants to give a score of 0 to answer the question. Based on Figure 7, DP means data preprocessing. In addition to Table 7, invalid imputations were found in the 'Online Learning Experience' attribute. In the 'Online Learning Experience' attribute, the response choices given are 'Y' (yes) or 'N' (no). Based on observations, there was one participant who gave a response 'n'. We think that participants intended to give an 'N' response so that instead of removing one of these observations, we changed the response n to 'N'. Some other cases about the non-uniformity of answers are caused by the use of capital letters. In the one-hot encoding method, the difference in one character results in the vector being arranged not the same even though it produces the same information [23]. Invalid imputation values cannot be further processed so they are deleted from the dataset. The number of observations is now equal to 1435 observations, shrinking from the previous stage (erasing missing values) of 1441 observations.

Figure 9: Comparison of the number of observations before and after data preprocessing

3.5. Post Observation

The post-observation phase aims to find out the number of observations after the data preprocessing treatment. Figure 9 is a comparison of the number of observations based on each faculty.

FMIPA is still the faculty with the highest number of observations and FIB remains the faculty with the fewest observations. Other faculties follow the same observation distribution. No faculty has a greater number of observations than other faculties after going through the data preprocessing stage. Based on this information, the data to be processed to the next stage can be said to have a valid observation distribution.

4. Results and Discussion

The questionnaire consisted of three parts, i.e., category A measures the ability of students to manage their e-learning environment, category B measures interactions students with online teaching materials, and part category C measures interaction among students and instructors within their learning community during the e-learning process. Before calculating the average value of each part of the questionnaire, the categorization of the level of preparedness will be determined first. The categorization has a goal to find out whether all students from each faculty have a sufficient level of readiness in learning to use e-learning or whether there are students from one particular faculty who feel unprepared because of the factors based on the given questionnaire.

4.1. Cluster Evaluation

The k-means algorithm divides the set of N samples consisting of X (observations) into disjoint clusters C_k (observations that have entered into one cluster cannot enter into another cluster). m_k is the centroid of each cluster. The value of m_k is not the same as the actual observation value even though they (observation and m_k) live in the same space. m_k is an artificial point. The error in Figure 10 uses equation 2. The equation aims to minimize inertia (the distance of observation to centroids in one cluster) can be referred to as a within cluster sum-of-squares criterion.

Figure 10: Elbow Methods for Optimum Cluster Number

The number of clusters is determined using the elbow method. This method requires human observation. The x-axis in Figure 10 is the number of clusters and the y-axis is the result of inertia calculation. Using the recommended elbow method, the number of clusters used in this study is equal to 3. Three Clusters obtained from the k-means algorithm are named cluster1, cluster2, and cluster3. Based on Table 8, the number of clusters with the most members is cluster2 and the number of clusters with the fewest members is cluster1. Visualization of the number of members in each cluster is given in Figure 11.

In Figures 11, the observation is closer to the coordinate point $(x; 0)$ where $x \in \mathbb{Z}$. x represents the observation index. The range of observations is the same for all clusters from 0 to 1433 (the

number is not the number of observations but serves as an identity). The quality of the formed clusters is studied further by applying two distance thresholds. We chose 10 and 5 as the threshold. We assume both values are close enough to the centroid in each cluster. The distance of each observation that is less than or equal to the threshold value is calculated in each cluster. The number of observations in each cluster is given in Figure 12. Based on Figure 12, $cluster_1$ has the least number of observations with the appropriate threshold distance.

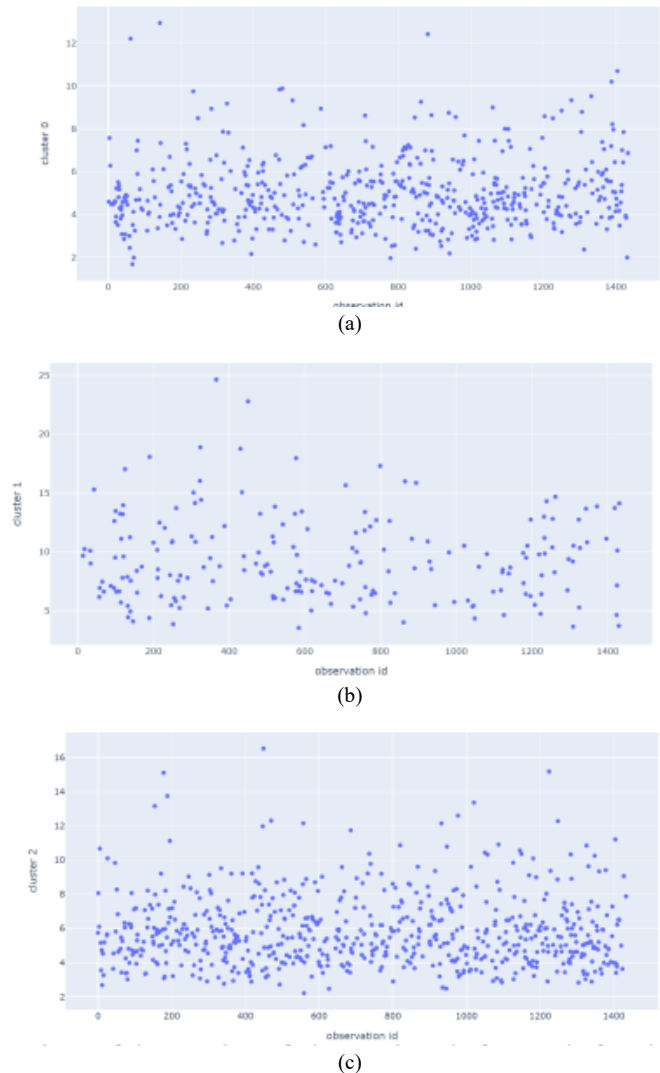

Figure 11: Comparison of the number of observations before and after data preprocessing

Figure 12: Comparison of the number of observations before and after data preprocessing

Table 8: Cluster Category Composition

Cluster	Number of Observations in Each Cluster
<i>Cluster₁</i>	564
<i>Cluster₂</i>	206
<i>Cluster₃</i>	665

Table 9: Cluster Composition

Category	Cluster		
	<i>Cluster₁</i>	<i>Cluster₂</i>	<i>Cluster₃</i>
A	7.88	6.79	8.77
B	7.89	6.74	8.82
C	8.10	6.76	8.96

Figure 13: Mean Score for Category A, B and C

4.2. E-learning Environment Readiness Level

To determine the categorization of these values, a k-means analysis is utilized. The results of the K-means analysis is presented in Table 9. The result suggests that the students' readiness is divided into three following categories:

- not ready, with a k-mean value below 7.5.
- ready, with a value between 7.5 to 8.5.
- very ready, which has a value above 8.5.

Based on the categorization levels of students' readiness to learn in the e-learning environment, the average value of each part of the questionnaire is calculated to determine the level of students readiness for each part. The mean scores are presented in Figure 13. The average score of category A is 8.093 out of 10, the average score of category B is 8,109 out of 10, and the average score of category C is 8.267 out of 10. As a result, participants are quite prepared in all three aspects of readiness.

To investigate further the differences of the students preparedness between faculties, the average scores of each part of the questionnaire was calculated for each faculty, as given in Figure 14(a), 14(b), and 14(c).

Figure 14(a) indicates that faculties having average scores above 8 are: Faculty of Economics and Business (FEB), Faculty of Psychology (FPSI), Faculty of Law (FH), Faculty of Administrative Sciences (FIA), Faculty of Nursing (FIK), Faculty of Social and Political Sciences (FISIP), Faculty of Medicine (FK),

Faculty of Public Health (FKM), Faculty of Mathematics and Natural Sciences (FMIPA), Faculty of Pharmacy (FARMASI), and Faculty of Engineering (FT). Faculty of Medicine has the highest scores of 8,271. Faculties that have mean scores below 8 are Faculty of Cultural Sciences (FIB) and the Faculty of Computer Science (FASILKOM). The average value for category A, management of e-learning environment, is above 8 (good) in some faculties, but for the FIB and the FASILKOM the student's perceptions toward their ability to manage an online learning environment need further improvement.

(a)

(b)

(c)

Figure 14: Mean Score for Category A, B and C for each Faculty

Similar to the mean scores for category A, Figure 14(b) depicts the mean score for category B. the Faculty having the largest mean score is the Faculty of Medicine, followed by faculties that have a mean score above 8: FEB, FKM, FMIPA, FPSI, FT, FIK, FIA, FISIP, FH. While the FASILKOM, FIB, FARMASI has a mean score of less than 8. The faculty that has the lowest mean score is the FASILKOM with a mean score of 7.6186. This fact is somewhat contrary to the fact that students of this faculty have high entrance test scores compared to other faculties, except the FK. In addition, students are directly exposed to subjects related to computer programming and mathematical foundations that are delivered by blended learning. One of the subjects is even done with intensive online collaborative learning. Delivery modes of

subjects in other faculties were mostly conventional with limited use of online interaction.

Figure 14(c) shows that the Faculty of Nursing (FIK) has the highest mean score of 8.6216, followed by FKM which has a mean score of 8.5287. Most faculties have mean scores above 8. The students of these faculties have a good level of preparedness. On the other hand, the Computer Science Faculty has the lowest mean score of 7.6645. The Faculty of Pharmacy also has low mean scores on category C.

Category A on the questionnaire discusses managing e-learning environments. General conclusions that can be drawn based on the average value of each category in each cluster are the participants involved in the interaction with the questionnaire capable of carrying out e-learning environment management. Of all the faculties at UI, an interesting finding was the performance of the Faculty of Computer Science (FASILKOM) which consistently scored low average scores in three categories. This leads to two specific conclusions about FASILKOM's performance:

- The measurement metric used is not representative. The method used is the calculation of the average of each category for all clusters. Note that the average value is sensitive to noise. For example, there are observations that fill in too high a value compared to other observations, so the average value of clusters in each category also increases rapidly. The number of participants from FASILKOM is only about 5% of all participants, so the difference is that if there is no large value that is able to shift the average value of FASILKOM, then the performance of FASILKOM is also difficult to pass number 8 like other faculties.
- FASILKOM has its own e-learning system 2 that acts as a central academic interaction. The experience filled out in the questionnaire is the participant's experience with this e-learning system. The e-learning system not only offers students interaction with subjects but also presents the latest faculty announcements, discussion forums, interactions between users of e-learning systems, etc. We argue that the system is considered more complex than e-learning which prioritizes the collection of tasks and grading only.

4.3. MPKT Learning Progress towards Syllabus Suitability

Figure 15 shows the graph of the mean score for part B questions, namely B_{14} (MPKT learning is carried out following Learning Reference Unit), B_{15} (The task and learning task loads of MPKT is following semester credit (SKS)) and for part C questions namely C_{22} (MPKT lecturer is able to facilitate online learning well). Figure 15 shows the average score of MPKT learning conformity items with SAP given (B_{14}) for each faculty studied. Based on the graph shows that FIA and FH have an average value for B_{14} above 8.5. FMIPA, FIB, FEB, FK, FPSI, FT, FIK, and FISIP have an average value for B_{14} above 8. Whereas the FASILKOM and FARMASI has average values for B_{14} respectively 7.344 and 7.938. This value has a considerable difference with other faculties which generally have an average value for item B_{14} more than 8.

This reveals that the conformity of MPKT learning with the Syllabus given is quite appropriate in some faculties indicated by the average value of item B_{14} has exceeded the value above 8, but the FASILKOM and FARMASI feels that the suitability between MPKT learning with the Syllabus given is not quite appropriate.

Therefore, at the Faculty of Computer Science and Faculty of Pharmacy, it is necessary to readjust the MPKT learning with the given syllabus.

Figure 15: Mean Score of MPKT towards Syllabus

Figure 16: Mean Score Task and Online Learning

Figure 16 above shows the average score for the item suitability of the workload and MPKT learning load with the number of SKS (B_{15}) for each faculty studied. Based on the graph above it can be seen that FMIPA and FIK have an average value for Task Load Suitability with Online Learning that is not too far away, FMIPA has an average value for item B_{15} (Matching Task Load with Online Learning) of 8.319 while FKM has an average the average value for item B_{15} (Matching Assignment to Online Learning) was 8.3392. Some faculties have an average value above 8, namely FIB, FK, FKM, FPSI, FIA, and FH, while other faculties have an average value below 8 such as the FASILKOM which has an average of 7.787 and Faculty of Pharmacy which has a value of the lowest average is 7.521.

According to the Figure 16, we can conclude that students of 5 out of the 13 faculties perceived that the task load and learning of MPKT were not enough according to the number of SKS MPKT, while the other faculties said that task load and learning process were by the number of SKS. This is indicated by the faculty's mean score of more than 8, but there are 5 other faculties with a mean score of less than 8.

4.4. Lecture's Readiness Perception

Figure 17 shows the average score related to the readiness of MPKT lecturers in facilitating online learning (C_{22}). Based on Figure 17 shows that faculties that have an average C_{22} value above 8.5 for items are FIB, FKM, FPSI, FIK, FIA, and FH. Faculties that have an average score above 8 are FEB, FK, FMIPA, and FT. while other faculties such as FASILKOM, FISIP, and Pharmacy have an average value for C_{22} items ranging from 7 to 8. The faculty with the lowest average value for item C_{22} is FASILKOM which is 7.279. This revealed that on average students agreed that MPKT lecturers could facilitate online learning, but for the three faculties namely FASILKOM, FARMASI, and FISIP students still felt that MPKT lecturers were not good enough to facilitate online learning. Therefore, it is necessary to improve the quality of MPKT lecturers in facilitating online learning.

Figure 17: Lecture Readiness Score in Online Learning

5. Conclusion

E-learning is a learning system that is increasingly needed today. Therefore, we conducted a first semester student questionnaire survey at the Universitas Indonesia environment in 2019. The three main aspects investigated: students' readiness to learn in an e-learning environment, the conformity of the MPKT syllabus to the learning process, and students' perceptions of MPKT teaching lecturer. Based on the data clustering using the k-means algorithm, we concluded the following.

- Students in each faculty is ready to learn in an e-learning environment. However, some students of the Faculty of Computer Science and the Faculty of Pharmacy require more additional time for preparation.
- Based on the average value of attribute B14 (MPKT learning is carried out following Learning Reference Unit), most students stated that MPKT learning was in accordance with the syllabus except for students of the Faculty of Computer Science and Faculty of Pharmacy. The average value of B14 of Computer Science students and Pharmacy students are lower than 8.
- Evaluation of participant responses to answer students' perceptions of MPKT lecturers was conducted on question C22 (MPKT lecturer is able to facilitate online learning well). Most of the students think that MPKT lecturers are able to teach well except in the Faculty of Computer Science, Faculty of Pharmacy, and Faculty of Social and Political Sciences who think that the teaching ability of MPKT lecturers need to be improved. This conclusion is also in line with Figure 2, where the Faculty of Computer Science and the Faculty of Pharmacy are more competitive as compared to entering other faculties.
- The study shows, in general, the students perceive themselves as being ready to learn in the e-Learning environment, except for students in one of the faculties who have been very intense using technology in their learning, including computer-related courses such as coding and doing online collaborative learning.

In general, there is an interesting phenomenon. The Faculty of Computer Science which is expected to give a high score in this survey actually has a low score. We argue that this is caused by inappropriate measurement metrics and e-learning complexity factors owned by the Faculty of Computer Science affecting the behaviour of participants. In addition, intensive e-learning and computer-related courses exposure may contribute to the students' perception on their readiness.

6. Recommendation

We propose future research that is expected to be able to discuss the readiness of teaching MPKT courses through in-depth discussion mechanisms both with students and MPKT expert

lecturers, measure the effect of the suitability of courses taken by students in the first semester along with MPKT courses, and an overview of the current situation of online learning in Universitas Indonesia.

Acknowledgement

We thank the subdirector of university courses administration Universitas Indonesia (UI) for allowing us to conduct a survey related to this research.

Lard

ABSTRACT

Biodiesel was produced from lard using a CaO catalyst derived from eggshells. The effects of catalyst loading and transesterification reaction time were investigated. The results revealed that the increase in yield of biodiesel occurred at all catalyst loading when the reaction time was increased. The optimal reaction time was obtained at 60 minutes. The results also indicated that there was an increase in yield of biodiesel when the catalyst loading was increased from 0.5% to 1%. Furthermore, increases in catalyst loading decreased biodiesel yields. The most optimum biodiesel yield of 92.69% was achieved when the reaction time, catalyst loading, methanol:oil molar ratio, reaction temperature, and pressure were 60 minutes, 1%, 6:1, 65 °C, and 1 atm, respectively. The FAME content in biodiesel product was 95.28%. The biodiesel obtained reflected a cetane number and heating value of 46.2 and 37.86 MJ/kg, respectively. Eggshell-derived CaO catalysts exhibited excellent reusability.

1. Introduction

Biodiesel is currently being developed as an alternative fuel on account of its many advantages over diesel oil, which include non-toxicity, environmentally friendly, biodegradability, high cetane number, and low emission [1, 2]. Biodiesel is a renewable resource composed of a mixture of various FFAE (fatty acid alkyl esters). Biodiesel, as a renewable alternative energy, can be made from vegetable oils and animal fats as a source of raw materials [3, 4]. Biodiesel can be obtained by esterification or transesterification process. Esterification process is the reaction of FFA (free fatty acids) with alcohol to produce FAME (fatty acid methyl ester) and water [5]. Transesterification is a reaction between triglycerides that can be obtained from oil derived from plants or fats from animals with alcohol to produce FAME and glycerol as a by-product [6, 7]. Esterification is carried out if the FFA content of the raw materials is higher than 2% [8, 9]. If the FFA content <1%, biodiesel synthesis is carried out by transesterification only.

Of the various types of vegetable oils, the most commonly used to produce biodiesel include rapeseed oil (in Canada), sunflower

oil (in Southern Europe), soybean oil (in the United States), palm oil (in South Asian countries, especially Malaysia and Indonesia), as well as castor oil (in India) [5, 10]. The utilization of animal fats as feedstock for biodiesel production has also been previously studied. Among the animal fats studied were lard, beef tallow, and fish oil [11, 12]. Compared to vegetable oils, biodiesel from animal fats shows several advantages, including high calorific value and cetane number [10]. However, biodiesel from animal fats also shows disadvantages, including high saturated fatty acid contents, plugging points and cold filter clouding point, which can cause problems during winter operations [11, 13].

Biodiesel synthesis from lard has been studied by several researchers [11, 13–18]. In [11] and [15], for example, the authors used KOH as a catalyst and produced biodiesel with FAME contents of 88.7% and 99.4%, respectively. In [18], the authors also used catalysts of 1.25% KOH and obtained a FAME yield of 96%. The biodiesel production from a mixture of soybean oil and lard using NaOH catalyst has been studied [13], which obtained a biodiesel yield of 77.8%. In [14], the authors investigated the transesterification of refined lard. The research was carried out in supercritical methanol. In this work, the transesterification process

*Corresponding Author: Luqman Buchori, Email: luqman.buchori@che.undip.ac.id

is carried out under reaction temperature conditions of 320-350 °C, reaction time of 5-20 min, methanol:oil molar ratio of 30-60, pressure of 15-25 MPa, and agitation speed of 0-1000 rpm. The results revealed a FAME yield of 89.91%. In [16], the authors explored the synthesis of biodiesel using immobilized *C. antarctica* lipase B as a biocatalyst. The biodiesel yield of 96.8% was obtained by a ultrasonic amplitude of 5 kHz, reaction time of 20 min, 1:4 molar ratio of fat:methanol and 6% (w/w of fat) catalyst level. Meanwhile, CaO as a catalyst has also been used in production of biodiesel by waste lard methanolysis [17].

In general, in the transesterification process, the researchers used a homogeneous catalyst in the biodiesel production from lard. The utilization of heterogeneous catalysts in the transesterification process, especially CaO, has not been widely developed by researchers. Calcium oxide is one of the most active and potential solid catalysts in the transesterification process. This catalyst can be reused, recyclable, inexpensive, non-corrosive, and environment-friendly; moreover, in methanol has low solubility, and a catalyst with high activity for the methanolysis reaction of oil [19, 20]. CaO can be obtained from calcination of waste shells, such as eggshells [21]. The utilization of eggshell as a catalyst in the production of biodiesel from lard has not been widely studied by researchers. Therefore, it is necessary to develop biodiesel production from waste shell, especially eggshells.

The aims of this study were to produce biodiesel from lard using CaO from eggshells as a heterogeneous catalyst, and to determine the effect of catalyst loading and transesterification reaction time. The characteristics of the biodiesel produced, including its density, cetane number, kinematic viscosity, and heating value, were then studied and compared with those of a biodiesel standard.

2. Experimental Methods

2.1. Materials

Methanol (99.9%, Merck) and lard were used as raw materials for biodiesel synthesis. Lard was purchased from a Johar market, Semarang, Indonesia. The reagent used for esterification was HCl (37%, Merck). CaO was prepared from eggshells obtained from restaurant waste around Tembalang, Semarang, Indonesia.

2.2. Catalyst Preparation

The eggshells obtained from the restaurant were rinsed using running water, and then cleaned with distilled water to eliminate dust and dirt. The clean eggshells were then dried in an oven (Mettler UN 55 B214.0281, Germany) at 105 °C overnight. Dry eggshells were crushed and calcined for 4 h in air in a Ney Vulcan muffle furnace (Vulcan Bench Top Furnace model D-550-240V) at 900 °C. The product obtained was CaO [21, 22] as a white powder.

2.3. Biodiesel Synthesis Using Esterification and Transesterification Process

Biodiesel synthesis was carried out by esterification and transesterification processes. Both processes were completed in a three-necked flask (Pyrex). This equipment was connected with a reflux condenser (Pyrex) and heater. Esterification aims to reduce the FFA content in lard. Methanol and oil were added to the three-

necked flask at 6:1 methanol to oil molar ratio. Thereafter, HCl amounting to 0.75% w/w of oil was added to the flask. The mixture was then stirred with a magnetic stirrer (Model No. SP131320-33 240V, Thermo Scientific) at 400 rpm while heating to 65 °C. Esterification was performed for 2 h. The esterification product was placed into a separating funnel and allowed to settle overnight. The product was then collected from the remaining methanol and acid catalyst.

The esterified lard was then reacted with methanol in a three-neck flask with methanol to oil molar ratio of 6:1. A number of CaO catalyst was loaded into the three-neck flask. Then, the mixture was reacted at 65 °C while stirring at 400 rpm. After the transesterification process was completed, the product was placed into a separating funnel (Pyrex) to be separated from the catalyst. The product was allowed to settle overnight to separate the biodiesel from excess methanol and glycerol. The glycerol at the bottom of the funnel was withdrawn, and the excess methanol in the top biodiesel layer was removed. Yield of biodiesel was determined by using (1);

$$\text{Yield}(\%) = \frac{\text{weight of biodiesel product (g)}}{\text{weight of lard (g)}} \times 100\% \quad (1)$$

Variables influencing the transesterification process, such as catalyst loading (0.5-7%) and reaction time (30-120 min), were also studied.

3. Results and Discussion

3.1. Esterification Result

During biodiesel synthesis, raw materials with high FFA contents require a two-step process, namely esterification and transesterification [7, 8]. In general, lard has an FFA content higher than 1% [16]; in fact, the raw materials analysis showed that the FFA content of lard was 10.05%. Thus, esterification is needed to decrease the FFA content of the raw material. The esterification process can decrease the FFA content of lard to 1.36%. To produce biodiesel, transesterification is then carried out.

3.2. Biodiesel Production Via Transesterification

3.2.1. Effect of transesterification reaction time

The effect of transesterification reaction time on biodiesel yield was investigated. The reaction time is an important parameter in biodiesel production [8]. The effect of reaction time on biodiesel yield can indicate the costs involved in producing biodiesel [23]. Here, transesterification reaction times of 30, 60, 90, and 120 minutes were applied. The experimental results were shown in Figure 1.

Figure 1 presents an increase in yield of biodiesel at all catalyst loadings and reaction times of 30–60 minutes. At the reaction time of 30 minutes with 1% catalyst loading, the biodiesel obtained was only 75.3%. This shows that at the reaction time of 30 minutes, the transesterification reaction has not reached equilibrium. This means that not all reactants have enough time to interact both between reactants and with the catalyst, resulting in lower biodiesel. Biodiesel yield increased and achieved its optimum at reaction time of 60 minutes. The optimum biodiesel yield was 92.69%. The experimental results reveal that a reaction time of 30 minutes is insufficient to complete the transesterification process.

Furthermore, at the reaction time after 60 minutes, there was a slight increase in the yield of biodiesel and it became almost constant. The increase in biodiesel yield is not significant. These results indicate that a reaction time of 60 minutes is sufficient to produce an effective biodiesel production.

Figure 1: Effect of transesterification reaction time on yield of biodiesel under various catalyst loadings (methanol:oil = 6:1; P = 1 atm; T = 65 °C)

The study conducted by previous researchers [15] also found that the optimal reaction time for production of biodiesel from lard was 60 minutes. In this study, the biodiesel yield obtained in the transesterification step was 97.2% at a KOH concentration of 2% wt and the ratio of methanol to oil was 9:1. In [17], the authors used a CaO-based catalyst from piglet roasting and quicklime during biodiesel production from waste lard and obtained a yield of 97.6% within 60 minutes. This finding reveals that the average transesterification reaction time needed for biodiesel production from lard via conventional methods was 60 minutes. Meanwhile, biodiesel production using supercritical methanol required 15 minutes of reaction to achieved 89.91% FAME content [14].

3.2.2. Effect of catalyst loading

The effect of catalyst loading on the transesterification process was studied by varying the CaO contents to 0.5, 1, 3, 5, and 7% (w/w) of lard with 6:1 methanol to oil ratio for 1 h at 65 °C. The resulting yield of biodiesel were presented in Figure 2.

Figure 2 shows that biodiesel yields increase when catalyst loading is increased from 0.5 to 1%. Furthermore, the higher the catalyst loading, the lower the biodiesel yield. The high catalyst concentration causes the mixture in the reactor to become too viscous. This fact results in more mass transfer resistance and therefore, perhaps some of the catalysts remain unused, which in turn lowers biodiesel yield [24]. In this study, an increase in catalyst amount causes the formation of a slurry from the mixing of the catalyst and reactants. The larger the amount of catalyst added to the reaction system, the more viscous the mixture becomes. As a result, higher power consumption is needed during the stirring process. Increased viscosity due to slurry formation must be prevented because it causes yield of biodiesel to decrease. In order for this problem to be avoided, it is necessary to determine the optimum amount of catalyst loading. The increase

in viscosity can also cause a slight soap formation which hinders the reaction process resulting in a decrease in yield. The results reveal that the optimum catalyst loading in this study is 1%.

Figure 2: Effect of catalyst loading on biodiesel yield at various reaction times (methanol:oil = 6:1; P = 1 atm; T = 65 °C)

Works that have been done in previous studies also indicated the same results [11, 18]. In [11], the authors applied KOH as a catalyst. The concentration of KOH varied at 0.6%, 0.9% and 1.2%. The results showed that the optimum biodiesel product with a FAME content of 88.73% was achieved at 0.9% wt KOH with a reaction temperature of 60 °C, a methanol-lard mole ratio of 6:1, and a stirring speed of 600 rpm. Meanwhile, in [18], the authors performed the optimization of lard oil methanolysis using a potassium hydroxide catalyst. The results showed that the optimum biodiesel yield was 96.2% at the amount of catalyst 1.25% under the following conditions: reaction temperature of 60 °C, reaction time of 40 min, the molar ratio of methanol to oil was 6:1, and stirring speed of 250 rpm.

3.2.3. FAME content of the biodiesel product

Optimal biodiesel production occurs under a reaction time of 60 minutes and 1%wt catalyst loading; these conditions produce an optimum biodiesel yield of 92.69%. The biodiesel product produced at these optimum conditions was analyzed using GC-MS (gas chromatography–mass spectrometry) (QP2010S SHIMADZU, DB-1 column) to determine its composition, and the results are presented in Table 1. The biodiesel obtained contained approximately 24 compounds, 15 of which were methyl esters.

Table 1: Composition of the biodiesel product

Peak	Retention time	Composition (%)	Name
1	20.276	0.02	Decanoic acid, methyl ester (CAS)
2	26.907	0.19	Dodecanoic acid, methyl ester (CAS)
3	32.676	0.95	Tetradecanoic acid, methyl ester (CAS)
4	35.299	0.04	Pentadecanoic acid, methyl ester (CAS)

5	37.186	0.18	9-Hexadecenoic acid, methyl ester, (Z)- (CAS)
6	37.312	0.67	9-Hexadecenoic acid, methyl ester, (Z)- (CAS)
7	38.035	22.08	Hexadecanoic acid, methyl ester (CAS)
8	38.778	0.03	Pentadecanoic acid (CAS)
9	39.658	0.09	9-Octadecenoic acid (Z)-, methyl ester (CAS)
10	39.914	0.19	Heptadecanoic acid, methyl ester (CAS)
11	41.888	11.07	9,12-Octadecadienoic acid (Z,Z)-, methyl ester (CAS)
12	43.118	53.75	9-Octadecenoic acid (Z)-, methyl ester (CAS)
13	43.634	5.47	Octadecanoic acid, methyl ester (CAS)
14	44.198	0.05	9-Hexadecenoic acid, methyl ester, (Z)- (CAS)
15	45.396	0.18	Methyl arachidonate
16	45.776	0.16	7,10,13-Eicosatrienoic acid, methyl ester (CAS)
17	46.186	1.95	Tridecanedial
18	46.796	0.37	Eicosanoic acid, methyl ester (CAS)
19	49.475	0.14	5,8,11,14-Eicosatetraenoic acid, ethyl ester, (all-Z)- (CAS)
20	49.773	1.16	Di-(9-octadecenoyl)-glycerol
21	50.414	0.65	Hexadecanoic acid, 2-hydroxy-1-(hydroxymethyl) ethyl ester (CAS)
22	53.237	0.05	3-(Dideuteromethoxymethoxy)-2,3-Dimethyl-1-Undecene
23	54.075	0.48	9-Octadecenoic acid (Z)-, 9-octadecenyl ester, (Z)- (CAS)
24	69.515	0.09	Cholest-5-en-3-ol (3.beta.)- (CAS)
		100.00	

According to Table 1, the FAME content in biodiesel produced from lard is 95.28%. This result is slightly lower than the standard purity of biodiesel according to EN 14214 [25] which is 96.5%, but higher than the previous studies [13]. In [13], the authors obtained a biodiesel yield of 47.2% with a purity of 92.0% under a reaction time of 3 h and a yield of 66.2% with a purity of 95.7% under a reaction time of 5 h. The findings thus far indicate that lard is a potential feedstock for biodiesel production because it can produce large amounts of FAMES.

3.2.4. Characteristics of the biodiesel product

Density, kinematic viscosity, cetane number, and heating value are important properties in biodiesel. These properties indicate the quality of the biodiesel fuel so that it will affect the utilization of this fuel. Density and kinematic viscosity directly influence the atomization process during combustion. Meanwhile, the ignition quality of the fuel is evaluated using a cetane number. Heating value is also known as gross calorific value. This property is commonly used to determine the energy content of fuels and their efficiency. The characteristics of the biodiesel obtained at optimum conditions are shown in Table 2.

Table 2 shows that the biodiesel product obtained has a density of 0.860 g/cm³. In the combustion process, a certain amount of fuel is injected into the combustion chamber. The amount of fuel

injected into the combustion chamber is influenced by the density of the fuel. Likewise, the air-fuel ratio is influenced by the density of the fuel. In the same volume, a denser fuel contains a greater mass. It means that a high density contains a high mass. Meanwhile, the fuel injection pump measures fuel by volume rather than by mass. Therefore, if the fuel density is too high it will affect the performance of the injection pump, as a result the combustion process becomes incomplete. The density obtained in this study has met biodiesel standards with the minimum standard of density being 0.860 g/cm³ and a maximum of 0.900 g/cm³.

Table 2: Composition of the biodiesel product

Fuel property	Units	Standard	Method	Experimental values
Density (25 °C)	g/cm ³	0.860 to 0.900	EN ISO 3675 [26]	0.860
Kinematic viscosity (40 °C)	mm ² /s	1.9 to 6.0	ASTM D445-19 [27]	4.48
Cetane number	–	47 (min)	ASTM D613-18a [28]	46.2
Heating value	MJ/kg	39.72	ASTM D240-19 [29]	37.86

Table 2 indicates that the kinematic viscosity of the biodiesel product obtained in this study is between the minimum and maximum standards of biodiesel. Viscosity is an important parameter of the biodiesel fuel produced. Viscosity affects the quality of atomization [4]. High viscosity can lead to poor atomization process. The viscosity of the fuel also affects droplet size. High viscosity has the potential to produce larger droplets at the time of injection so that the atomization process is disturbed, as a result of which the spraying becomes poor. Poor atomization results in poor combustion which increases exhaust fumes and fuel emissions. Fuels with high viscosity also result in the need for more energy to pump fuel and can cause deposits in the engine. The kinematic experimental value of the viscosity produced in this study was 4.48 mm²/s. This value is still below the maximum value required by the ASTM D445-19 specification (6.0 mm²/s).

The cetane number, defined by ASTM D613-18a, is a measure of the auto-ignition delay time of the fuel. Diesel engines desirable high cetane numbers. A higher cetane number results in a shorter time between ignition and initiation of the fuel injection. The high cetane number also ensures the engine is started and running properly and smoothly. In contrast, a low cetane number causes incomplete combustion which tends to increase gas and particulate emissions which in turn result in air pollution. The cetane number value generated in this work is 46.2. This cetane number is slightly lower than the minimum biodiesel standard required, which is 47. This is probably due to the double bonds of fatty acid compounds. Compounds with double bonds can cause a lower cetane number [30]. The results of GC-MS analysis show that the biodiesel product obtained contains several compounds with double chains, such as 9,12-octadecadienoic acid and 9-octadecenoic acid, which could reduce its cetane number.

Table 2 also reveals that the heating value of the biodiesel obtained in this study is 37.86 MJ/kg. The heating value describes

the amount of heat produced from the fuel combustion with oxygen [4]. At the initial temperature, this combustion produces CO₂ and H₂O. The higher the heating value, the less the amount of fuel needed to produce combustion heat. Thus, the higher the heating value, the more efficient the use of fuel. Increasing the amount of carbon in the fuel molecule will increase the heating value of the fuel. The increase in heating value is in line with the increasing ratio of carbon and hydrogen to oxygen and nitrogen [4]. The heating value of the biodiesel product obtained in this work is approximately 4.68% less than that of biodiesel standard and 11% less than petrodiesel, which has a heating value of 42.7 MJ/kg.

3.3. Catalyst Reusability

One method to determine the stability of a heterogeneous catalyst is to test the recyclability of the catalyst. The reusability of the catalyst was carried out in conditions where the transesterification process produced optimum biodiesel yield, namely the reaction temperature of 65 °C, the mole ratio of methanol: lard of 6:1, the catalyst loading of 1% and the reaction time of 1 h. The catalyst that has been used in each cycle was separated by filtering and then washed with methanol to remove adsorbed material. The catalyst was then recalcined at 900 °C for further use. The results of the catalyst reusability were shown in Figure 3.

Figure 3: Effect of catalyst reusability on biodiesel yield (methanol:oil = 6:1; P = 1 atm; T = 65 °C; catalyst loading = 1%, reaction time = 60 min)

Figure 3 shows that the biodiesel yield decreases with increasing catalyst use cycles. Nevertheless, the catalyst can be reused after six consecutive runs with excellent activity in the lard transesterification reaction for biodiesel production. The biodiesel yield obtained was still above 90%. However, in the seventh run the biodiesel yield was found to have decreased below 90%, which was 85.67%. The decrease in biodiesel yield after each run may be due to the blocking of the active sites on the catalyst surface by the deposition of unreacted oil, biodiesel or glycerol [24]. These results indicate that the CaO catalyst derived from eggshells has a high potential to be used as a catalyzing for biodiesel production with good reusability.

4. Conclusion

Biodiesel can be obtained from lard in high yields. The reaction time of transesterification required to obtain biodiesel is only 60 minutes with 1%wt catalyst loading. The biodiesel yield produced from this study was 92.69% with the FAME content was 95.28%. The fuel properties of biodiesel products that meet the established standards are kinematic viscosity and density. Meanwhile, the heating value and cetane number obtained in this work are slightly lower than those of the biodiesel standard. In the transesterification process, the CaO catalyst derived from eggshells is able to maintain its catalytic activity after being reused 7 times. The results generally prove that biodiesel synthesis from lard using a heterogeneous catalyst, specifically CaO from eggshell, is an acceptable strategy.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

We would like to thank the Faculty of Engineering, Diponegoro University, Indonesia who financially supported this research through the Strategic Research Grant.

SQL Injection

Web Application Firewall

WAF

ABSTRACT

The security of website application has become important in the last decades. According to the Open Web Application Security Project (OWASP), the SQL Injection is classified as one of the major vulnerabilities found in web application security. This research is focused on improving website security in dealing with SQL Injection attacks by stopping, monitoring, and dividing types of SQL Injection attacks using the features provided by the proposed Web Application Firewall (WAF). The architecture is designed to detect and prevent some types of SQL Injection attacks, including Tautologies, Logically Incorrect Queries, Union Queries, Piggy Backed Queries, Stored Procedures. For the testing scenario, this experiment uses an application that has become an industry standard in identifying and validating security holes on a website. The result of this research is that the proposed system is able to increase the website security from SQL Injection.

1. Introduction

The growth of technology has been evolved tremendously in many aspect. One of the examples is the World Wide Web evolve from 1.0 to 6.0 [1]. It shows that this evolution also needs to improve the web security. Nowadays, cyber criminals have exploited the COVID-19 pandemic situation to launch a highly sophisticated cyberattacks in every industry. In the first quarter of 2020 (Q1 2020), even 8.4 billion records have been revealed [2]. Data breaches frequently occur at various companies, ranging from small-scale companies to large-scale companies such as eBay, TJX Companies, Inc., Uber, JP Morgan Chase, Sony's PlayStation Network, Home Depot, Adobe, and many others [3]. Those companies use the web applications and web services that can be accessed online, and their application are also exposed to the public. Most web attack target the vulnerabilities of web applications [4].

OWASP (Open Web Application Security Project), a non-profit foundation that works to improve software security, has announced the top 10 Web Application security risks. Based on these data. It is further stated that the highest level of security risk in web application is injection [5]. Those injections can occur when some suspicious data is sent by a command or query. Injection consist of SQL (Structured Query Language), NoSQL, OS (Operating System), and LDAP injection. As one of the common injections, SQL Injection is to cheat the server to execute malicious SQL commands like CRUD (Creating, Reading,

Updating, Deleting) by inserting SQL commands into the query string of Web form submission or input domain name or page request [6], [7].

There are several types of SQL Injection including Tautologies, Logically Incorrect Queries, Union Queries, Piggy Backed Queries, Stored Procedures [8], [9]. Tautologies is an attack to produce TRUE condition by using '=' (equal) to the query. This type of SQL injection can bypass the authentication page and get the extracted data. The next type of SQL Injection is Logically Incorrect Queries. This attack tries to gather information about the database by injects query with type mismatch, syntax error or logical errors. This attack will generate an error message with some useful debugging information. While for Union Queries is an attack to combine two or more queries by using UNION syntax. They used the 'union' keyword to combine the original query and injected query and get some information from database. Piggy Backed Queries is an attack to inject additional queries to the original query. For this injection, the attacker tries not to modify the query, but they execute multiple queries which may lead to Database exploitation. The last type of SQL Injection is Stored Procedure. Stored Procedures is an attack execute or create stored procedure in database. This will result in remote commands and a denial of service.

This paper contributes to detecting 5 types of SQL injection attacks, including: Tautologies, Logically Incorrect Queries, Union Queries, Piggy Backed Queries, Stored Procedures. This paper also contributes to the development of a web-based-

www.astesj.com

<https://dx.doi.org/10.25046/aj060247>

application that can block the attacker's IP either manually or automatically, and an additional map feature that can show the number of attacks from various countries based on their IP addresses. In addition to increasing security, this could benefit the SecOps (security operations) in analyzing SQL Injection attacks.

2. Recent Work

Several works have been done to prevent the attacks on SQL injections. In 2020, Hlaing and Khaing presents an approach which detects a query token with reserved words-based lexicon to detect Structured Query Language Injection Attacks (SQLIA). The proposed system is done by using two approaches, which are: creates lexicon and tokenize the input query statement and each string token was detected to predefined words lexicon to prevent SQLIA. Based on the experiment conducted, the proposed system is able to provide a successful prevention from various malicious query for injections [10].

Another research comes from [11] the authors introduce the principle of SQL injection attack: The main form of SQL injection attack, types of injection attack and how to prevent SQL injection. In general, there are several types of SQL injection attacks: the escape character is not filtered correctly, incorrect type handling, vulnerabilities in database servers, blind SQL injection attack, conditional errors, conditional response, and time delay. They also proposed some codes to prevent SQL injection.

In [12], the authors analysed some methods of detecting and preventing the SQL injection attacks such as AMNESIA, SQLCHECK Approach, CANDID, Auto-mated Approach, WASP, Swaddler, Tautology Checker, WebSSari and Ardilla. Based on the research conducted, it can be implied that the structure of developing web application must be considered carefully to avoid various types of SQL injection attacks.

In another study, [13] the author proposed a secure coding approach that can be used by the developer for the prevention of SQL injection attacks to secure their application. They focus the research for prevention of SQL injection attack on: Input and URL validation, data sanitization, prepared statement (or PDO) for query execution, Query, and session tokenization. The result of the proposed research proved to be very effective and efficient in preventing different types of SQL injection attacks.

In 2019, the authors explained, detected, and described the various risk prevention mechanism Injection from the top ten vulnerability risk of OWASP, including, SQL Injection, Broken Authentication, Sensitive Data Exposure, XML External Entities, Broken Access Control, Security Misconfiguration, Cross-site Scripting, Insecure Deserialization, Using Components with Known Vulnerabilities, and Insufficient Logging and Monitoring [14]. They also explained how the attacker identify the vulnerability code and describe some injection risk prevention methods in the web application.

3. Proposed Method

The proposed web application firewall aims to detect and prevent the SQL injection attacks. Several types of SQL injection attacks that can be detected by the proposed system are tautologies, piggy-backed, stored procedures, union query and logically incorrect query. The architecture designed of proposed web application firewall uses Server Resident (or Embedded WAF), where the firewall installed on the host executing the web server [15]. This architecture places the WAF on the server, as it can be seen at Figure 1.

Figure 1: Server Resident Architecture

Based on the Figure 1, the WAF represented by the shield, installed on the protected server. By applying this topology, WAF can protect clients that runs the web service from SQL injection attacks. Figure 2 represents the server resident architecture applies on the proposed system (SEA WAF).

Figure 2: SEA WAF Architecture

The architecture of the proposed Web Application Firewall can be seen at Figure 2. Based on the architecture, firstly, the user/hacker uses the internet connection to access the website the goes through the network firewall and after that, the server will receive the requests from the user/hacker. When a request comes into the server, the request will be filtered first by the proposed firewall (SEA WAF). Furthermore, the SEA WAF will filter the 5 different types of SQL Injection attacks, which are: tautologies, piggy-backed, stored procedures, union query and logically incorrect query. If the request is marked as safe from the 5 types of SQL injection attacks that have been mentioned before, then the request will be continued to the client web service. However, if the request is marked as dangerous, then the request will be dropped, and a blocked message will be appeared. Some of the features that available in the SEA WAF application, including view a list of visitor requested on the website, remove the attacker from the blocked list, check the attack state based on the attacker's IP address, manually block the attacker, change the safe request to unsafe request according to the user, automatically block the attacker based on the number of attacks carried out, set up the activation of SEA WAF and manual setting for blocking the attacker.

To find out if the proposed web application firewall can prevent the SQL injection attack, this research use an e-commerce website that build with PHP Laravel Framework called AEShop as

targeted website. AEShop is an online website that uses a concept such as a department store with a one stop fashion theme. This online shop offers various types of clothing in both of male and female categories. For the test scenario, the SEA WAF is installed on the AEShop website using the burp suite application [16] to check if the proposed system is capable of handling the SQL Injection attacks. To provide a brief overview of the existing WAF applications, this paper also conducted a feature comparison that handles SQL Injection attack problems, with the application comparison including CloudFlare and Barikode WAF.

4. Experimental Result

In this section we compare two Web Application Firewall. CloudFlare (<https://cloudflare.com>) and Barikode (<https://ethic.ninja>). CloudFlare (Figure 3) is a Content Delivery Service that use as Web Application Firewall as well. CloudFlare sits in the middle between domain and web hosting. CloudFlare uses a set of rules to filter and monitor HTTP traffic between web applications and the Internet. As a third-party intermediary for the domain and web hosting, CloudFlare also plays a role in minimizing the threat such as Brute Force Attack, Cross-site Scripting, and SQL Injection as well [17]. In this research we will focusing on SQL Injection threat. CloudFlare only prevents certain SQL Injection, Tautologies, Logical incorrect and Piggy backed queries.

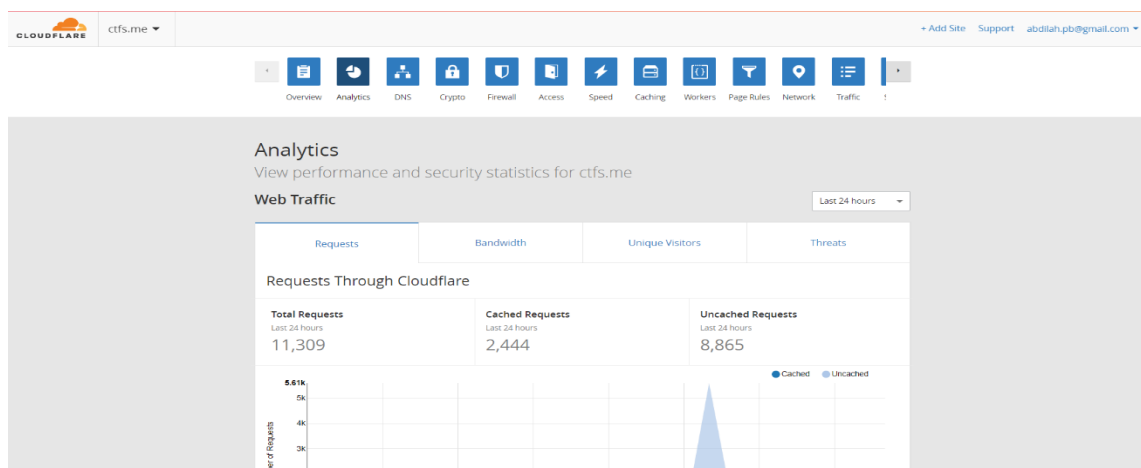

Figure 3: CloudFlare Admin Panel

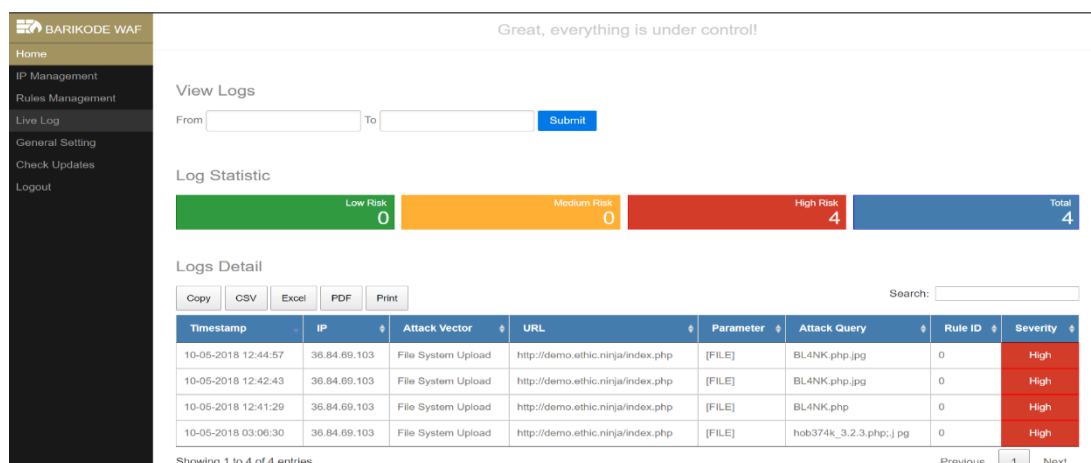

Figure 4: Barikode WAF Admin Panel

The second app Barikode WAF (Figure 4) is a website-based firewall that guard both public and internal websites (ERP, sisfo, etc.). Barikode has the ability to detect attacks by hackers early, monitor live traffic, and detect malicious scripts (shells / backdoors) that have been planted by hackers [18]. Barikode WAF can be install on any CMS or PHP Framework such as Laravel, CodeIgniter, Wordpress, Joomla, etc. In the security area, Barikode WAF can prevent threat like SQL Injection, XSS, local file inclusions, and remote code execution. For the SQL Injection threat Barikode WAF only cover Tautologies and Logical Incorrect Queries.

Table 1: Attack Type Comparison Result

Attack Type	CloudFlare	Barikode WAF
Tautologies	✓	✓
Logically Incorrect Queries	✓	✓
Piggy Backed Queries	✓	
Union Queries		
Stored Procedures		

Based on the Table 1, the CloudFlare and Barikode WAF applications only detect the tautologies, logically incorrect queries and Piggy backed queries Injection (Piggy backed queries only

works for CloudFlare application). While for the union queries and stored procedures injection, both CloudFlare and Barikode WAF applications are unable to prevent these two types of attack. Therefore, the SEA WAF application is designed to be able to detect and prevent five types of SQL Injection attacks, which are: Tautologies, Logically Incorrect Queries, Piggy Backed Queries, Union Queries and Stored Procedures.

5. Result and Discussion

The result of this research is a web application firewall called SEA WAF that can prevent SQL Injection. SEA WAF have several web pages to help administrator to manage the data. After user login, SEA WAF will display a dashboard (see Figure 5) containing important things including five types of SQL Injection attacks with a total of attacks from each type of SQL Injection, a list of five IP addresses based on the highest number of accesses, and then a box containing the name of the country and the total attacks received based on sending attacks from the IP address location. Then finally there is a line graph box that contains the number of attacks received by websites that have been accumulated for each month.

As can be seen in Figure 6 regarding IP management page, there are IPs that have attacked the website and were blocked by SEA WAF. There is a function for manual blocking on this page by entering the IP address that is suspected of carrying out the attack and determining the blocking period by pressing the block button. User can also see the country from their IP address and delete IPs that have been blocked so they can re-access the website.

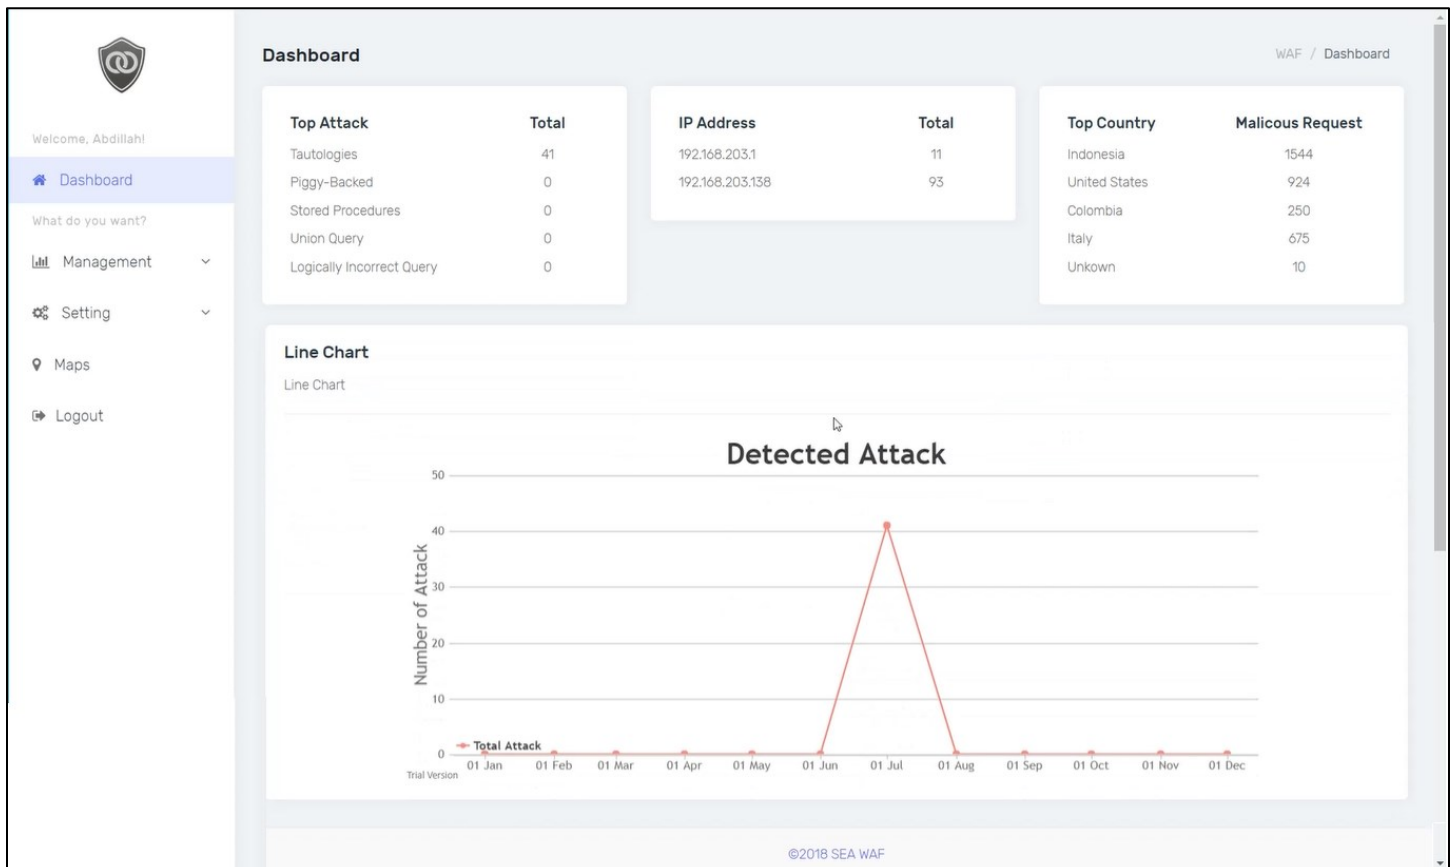

Figure 5: Dashboard

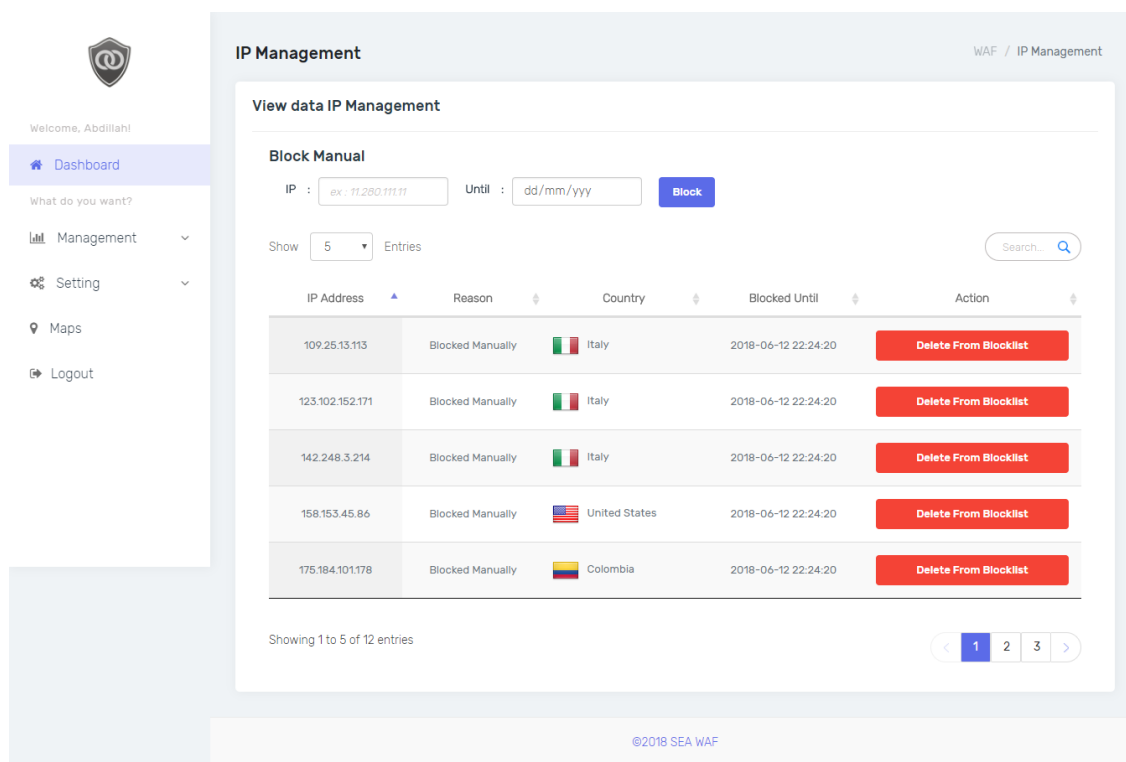

Figure 6: IP Management

Based on the Figure 7 (Log Management page), user can see log of each activity of the targeted web. There are several information about the activity including HTTP method, URL, Query String, IP Address, and Detection. If the activity categorized as one of the SQL Injection attacks, then it will be marked “NOT SAFE: [SQL Injection Type]”. User also can mark as safe, mark as malicious, or block the IP address.

The world map page shows the map with number of attacks based on the location of the IP address (Figure 8). If the user hovers the cursor to the map area, the name of the country and the total number of attacks the website has received from that country will appear. This map categorized attack by level of risk, from No Risk/Clear Risk (Green colour) to High Risk (Red colour).

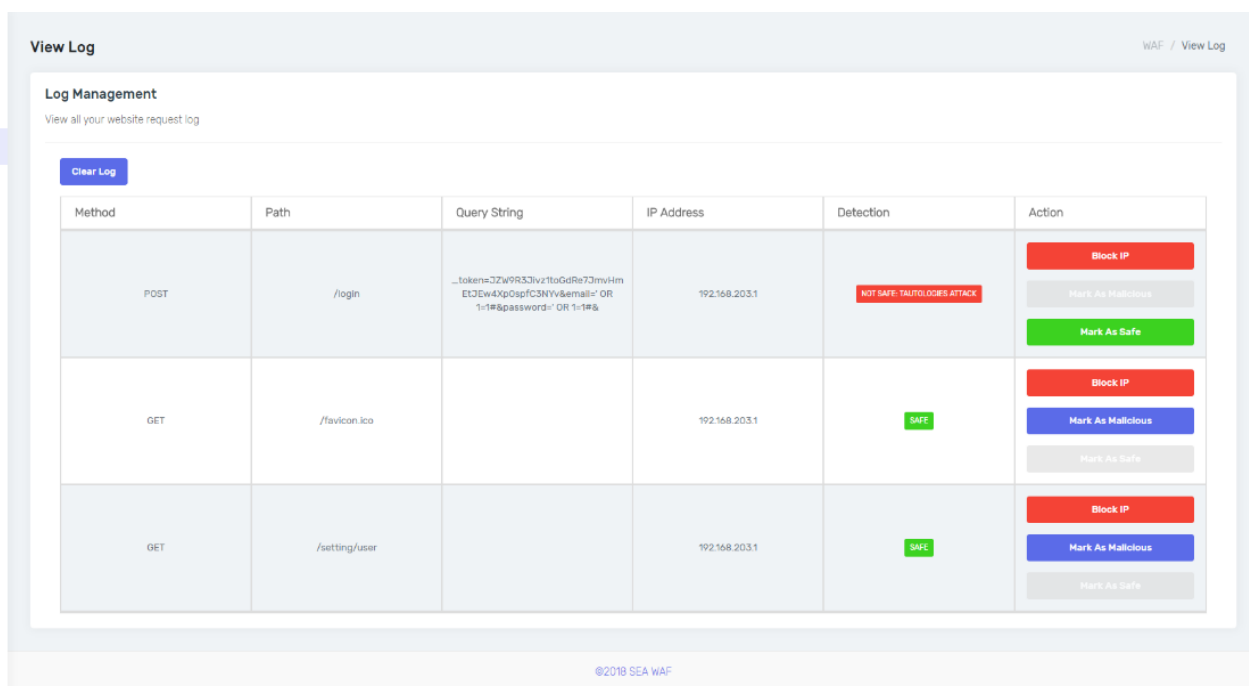

Figure 7: Log Management

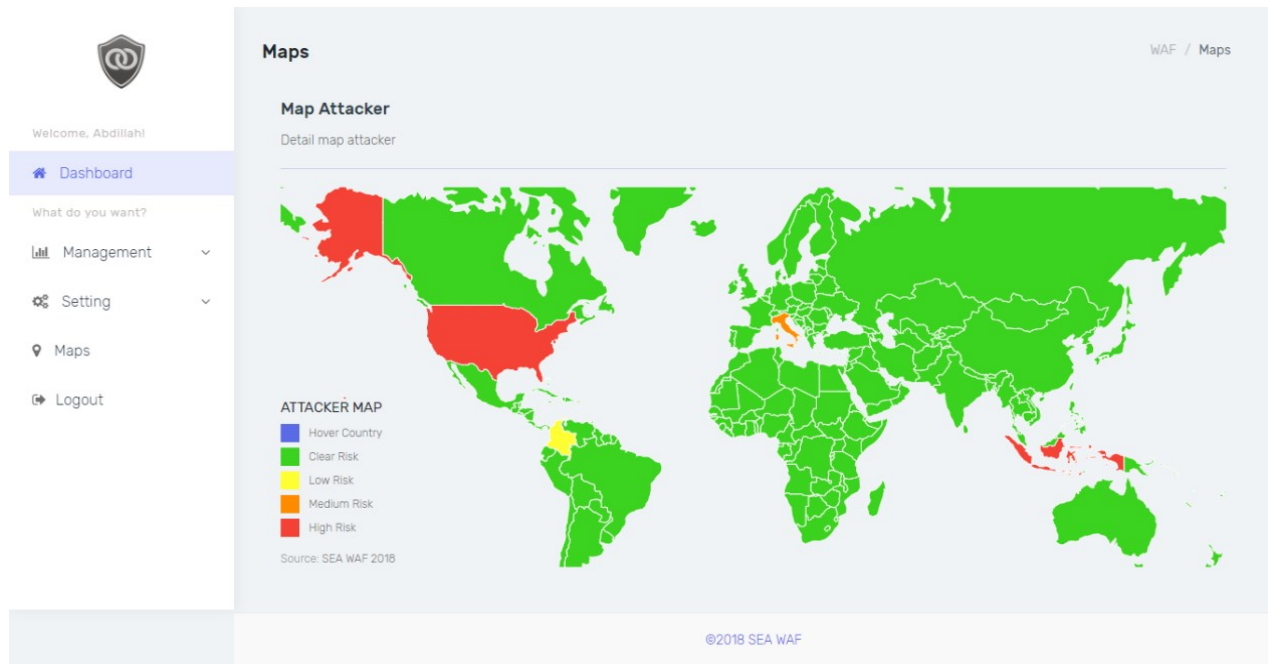

Figure 8: World Map

6. Testing

As part of the research, testing is important activity to see the result of the method. This research uses an e-commerce web called AEShop as targeted web. Based on Figure 9, we can see the web have an URL webdummy.test and it view kind of products.

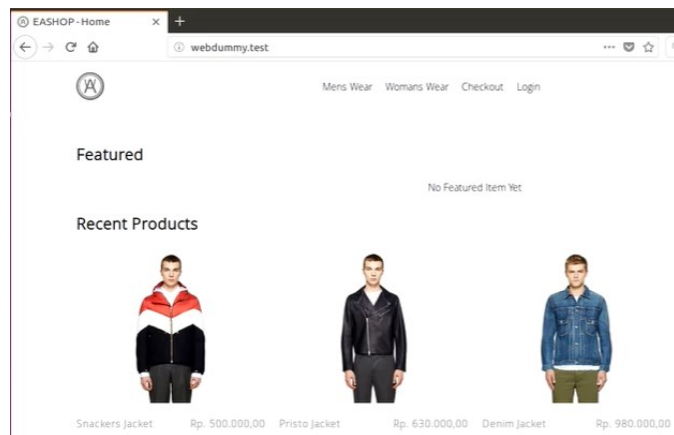

Figure 9: AE Shop

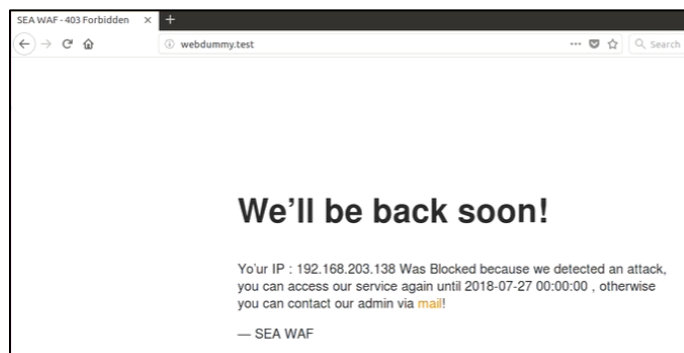

Figure 10: Blocked Message

Then if there is SQL Injection attack from the user, SEA WAF will detect and block it automatically. Then the IP address of the user will be blocked, and user will get the block message (See Figure 10). User cannot access the web until admin remove the block or the block is expired.

By using the burp suit application, the functionality of the SEA WAF application can be seen whether it is able to identify and block SQL injection attacks. The following Table 2 shows the application testing in blocking SQL Injection attacks.

Table 2: SQL Injection attack testing

No	Condition	Result
1	A tautologies-type SQL Injection attack occurred on the AShop website	The SEA WAF application detect and block the tautologies-type SQL Injection attack
2	A piggy-backed-type SQL Injection attack occurred on the AShop website	The SEA WAF application detect and block the piggy-backed-type SQL Injection attack
3	A stored procedure-type SQL Injection attack occurred on the AShop website	The SEA WAF application detect and block the stored procedure-type SQL Injection attack
4	An union-type SQL Injection attack occurred on the AShop website	The SEA WAF application detect and block the union-type SQL Injection attack
5	A logically incorrect query-type SQL Injection attack occurred on the AShop website	The SEA WAF application detect and block the logically incorrect query-type SQL Injection attack

Based on the Table 2, the SEA WAF application is able to identify and block five types of SQL Injection attacks, including Tautologies, Logically Incorrect Queries, Piggy Backed Queries, Union Queries dan Stored Procedures. The comparison with the other applications (CloudFlare and Barikode) can be seen in Table 3.

Table 3: SQL Injection attack testing

Attack Type	CloudFlare	Barikode WAF	Proposed Application (SEA WAF)
Tautologies	✓	✓	✓
Logically Incorrect Queries	✓	✓	✓
Piggy Backed Queries	✓		✓
Union Queries			✓
Stored Procedures			✓

As can be seen in Table 3, the proposed application can detect all five types of SQL Injection attacks, while for the other applications (CloudFlare and Barikode), it can only detect certain types of SQL Injection attacks.

7. Conclusion and Future Work

The growth of digital brings increase in web application, as well as the web attack. The security of the web needs to be improved, especially in SQL Injection attack that is the top risk security. SEA WAF bring the solution to secure the web from 5 type of SQL Injection attack automatically. Other features can help administrators to add more security manually such as block by IP or mark any suspicious traffic by Mark as Malicious. With simple and easy to use interface can help administrator or even the normal user to manage the security easily. For future research, this application needs to add more features like notification system to administrator, reporting, and expand for more varieties of injection attacks, such as NoSQL, OS (Operating System), or LDAP injection.

Conflict of Interest

The authors declare no conflict of interest.

Dynamic Optimization Problem

ABSTRACT

Quality of service is a significant part of formulating a composing of web services to satisfy the user's request, especially when several services exist and have been implemented in the same field and functionality. The selection process of web services among many options can be taken based on the quality of service considerations, fitness parameters, multiple objectives, and constraints. Moreover, some non-functional factors such as quality of service indicators such as integrity, cost, availability, reliability, security, and response time. Several composite services are required to achieve the user's requirements. This paper presents an integrated approach based on immigrant schemes and multi-objective genetic algorithm (ISMOGA) to specify and maintain the diversity of composite services more efficiently. Research experiments evaluate the performance of elitism-based ISMOGA based on different probabilities of immigrant mutation to produce an adaptive mechanism and to improve the performance in the dynamic optimization problem. The proposed method is compared to the standard technique of genetic algorithms and multi-objective algorithms. The experimental results show that ISMOGA outperforms other algorithms and improves the searching process. Moreover, the proposed algorithm can quickly adapt to the different resources and environmental changes as well as increases the high-quality solutions to satisfy QoS requirements in different configuration networks and communications channels.

1. Introduction

Distributed services based on systems and functions targeted in several stages of implementation and deployment have differences in non-functional features related to availability, reliability, response time, and performance are used as measures tools of Quality of Service (QoS) [1]. There are several selections to substitute each service with others when a user is mapping a service chain to a specific one by using a request and a response method.

Decision selections affect the behavior of workflow events assigned to QoS that require the deployment phase not to be chosen randomly. The selections should be considered according to QoS requirements such as security process, commercial integrity, main objectives, and constraints. The main challenge is the selection problem of the QoS.

The QoS-based web service contains many challenges that can be represented by different types of optimization methods. The QoS of hybrid web services were used in different fields such as business, academic, transport, monitoring, exchange information, service registering, and web services industrial.

The hybrid web services and location systems introduce a set of advantages related to the mobile application and customers to get benefit information about scheduling problems, resource allocation, and analysis data to retrieve essential and useful information to customers [2]. GPS and GPRS systems in mobile phone and web service applications are used to support location-based services for providing high-quality services. The location-based services are implemented via Google Web Service. GPS System is proposed to provide a high scale of QoS for web services [3]. Creating a web service is an attractive feature of web services that have been integrated into existing web services to

create a new value-added set of web services to meet user needs and customer requirements.

Web services architectures can be used as a functional application to be implemented in developing composition web service programs. A service application can be integrated into a single process that is included as a set of web services applications to run automatically together. The process of developing technologies to create compositions of web services from many candidate services is a significant cost and time-consuming.

The solution to creating composition problems based on multi-objective characteristics is evolutionary computing. Therefore, researchers in [4] proposed applying Multi-Objective Genetic Algorithms (MOGA) for optimizing service quality using effective solutions. Researchers focus on the main vital QoS issues that rely on web services as follows.

- Web services problems can be increased when creating a composite service with individual services used by external providers.
- QoS problems can arise when using cloud services that are part of hybrid cloud services to construct composite web services.
- QoS problems can arise when scheduling and resource allocation are used in multiple objectives of QoS for web services systems.
- Scheduling composite web services with multi-objectives is very complicated. Scheduling results could be sophisticated and inaccurate with respect to the QoS of web services.
- Planning and organizing composite web services will be very hard. The number and size of composite web services increase the problem.

In the general perspective and according to the research theory of composite web services, the complex problem is related to a scheduling problem, resource allocation, and QoS attributes, so the problem, in this case, is NP-hard problems.

MOGA is used to generate acceptable solutions to optimize composite problems when the search space cannot be determined efficiently using methods of traditional optimization, such as heuristic methods. MOGA operates on an individual's population, for each population could be generated as a possible solution for the optimization problem. Individuals are evaluated by applying their fitness function [5]. The fitness level is used to indicate how well a population individual can be solved the optimization problems [6]. Researchers develop and enhance web service technologies that can provide a way to use various applications based on web service composition [7].

This paper aims to achieve web services based on the highest level of quality to satisfy multi-objective QoS-based constraints and reduce response time at the lowest cost and maximum reliability. Besides, the quality criteria of web services will be optimized at the same time. Moreover, this study focuses on how to apply the proposed ISMOGA algorithm to complex web services. It can be used to develop and improve service quality based on dynamic web optimization problems to increase throughput and reduce execution time and costs.

2. Literature Review

In [8], the authors proposed an algorithm to ensure that software distribution providers are able to manage the dynamic requirements of customers. Besides, they suggested building a map of customer demands to meet various levels of infrastructure in homogeneity and heterogeneity systems. Scheduling mechanisms are designed and implemented to ensure that the scheduling mechanism determines, which type of VM can be initiated to incorporate the heterogeneity of VMs. The approach did not consider the service discovery process, but rather suggested methods of allocating resources to software as a service (SaaS) providers to reduce costs of infrastructure and service level breaches.

Several solutions related to the service selection problem have been formulated in [9]-[11]. This problem consists of locating the group of concretizations to satisfy all QoS constraints that are required by customers.

In [9], a new approach uses Genetic Algorithms (GAs) was proposed to identify a collection of concrete services to restrict abstract services and workflow stages of a composite service to perform QoS constraints established in the service-level agreement (SLA). This approach aims to optimize the function of QoS parameters. The authors did not determine the necessary number of resources selection while the service discovery is discarded in the mapping resource selection. Authors in [10] have proposed a service selection approach without determining the resources set to run the selected services to satisfy the QoS restriction and constraints, therefore the proposed research is not achieved in the services of cloud computing. An optimization evolutionary multi-objective related to service composition as a framework has been proposed in [11]. The proposed framework illustrates a service deployment model to apply two multi-objective genetic algorithms: Extreme-E3 (X-E3) and E3-MOGA. These algorithms have been produced a set of Pareto solutions to satisfy SLAs of service compositions. X-E3 and E3-MOGA locate the number of instances for each concrete selected service to satisfy a certain SLA during the workflow definition and a series of abstract services.

3. Genetic Algorithm

A standard Genetic Algorithm (GA) is a search heuristic of natural selection based on the fittest of individuals. GA has a set of parameters such as a population and candidate solutions, called individuals or creatures. The optimization problems of a genetic algorithm are the better solutions based on a fitness function. The candidate solutions have a set of genotypes or chromosomes, which are mutated. The population individuals of the genetic algorithm can be represented as concrete services. Therefore, the selection individual problem represents a candidate of abstract service. Fitness function is an evaluation measure of a genetic algorithm to select population individuals to get more evolution and feasible solutions of the composite web services [12].

The optimization problems of GA are defined as a constrained and dynamic optimization problem to select the highest QoS of composite web service, the customer's preferences, and to ensure

that a composite web service satisfies the cloud customer resources to guarantee the QoS constraint. This paper uses the MOGA algorithm to solve multi-constraint problems and to apply immigrant schema based on MOGA to produce feasible solutions. It is used to achieve high quality after each change as well as to satisfy all required constraints.

3.1. Genetic Algorithm steps

Five steps are considered in a genetic algorithm:

- Creating an initial population randomly, which consists of a set of individuals according to the available data that must be resolved.
- The fitness value is computed for each individual and then compared to the best fitness value to replace the best value in case the obtained fitness value is better than the previous value.
- Selecting the fittest individuals based on their fitness scores. The individual's migration is performed based on fitness values.
- Crossover processes are performed on parents, which leads to the generation of new individuals.
- The mutation operator is applied randomly to one of the individual characteristics; therefore, the status value is changed to a random value within the terms of population individuals.

3.2. Fitness Functions Calculations

There are a set of individual instances in GAs. The individuals are instances of the Combination of Services (CS), so the fitness values of individuals will affect the probability of being selected individuals. Therefore, the main technique of GAs is the calculations of fitness functions, and the selection of individuals based on global QoS constraints dependent on the user's preferences. The global constraints of QoS are significant references for the fitness function [13]. The user's preferences and the selection rules must be considered to build fitness values, such that the individual fitness value and the individual's selected probability are maximum.

3.3. Developed Genetic Algorithm

This paper improves GA to perform the selection of service composition. GA includes creating and encoding processes using a tree graph for selection parameters and applying the fitness function strategy. The tree encoding method represents a tree graph of services composition between the source of abstract service and multi-destination of concrete services.

There are different types of service composition such as series composition, parallel composition, probability composition, and circulation composition, which are included in the service combination process. A structure of a special tree is used to present the service combination, which is called a tree combination.

4. Design GAs for Dynamic Optimization Problem

This section describes the proposed ISMOGA algorithm for the Dynamic Optimization Problem (DOPs) in the web services composition. The ISMOGA design involves a set of key functions such as individuals' representation, initialization values, fitness functions, selection parameters, immigrant scheme, crossover, and mutation. The abstract service consists of a sequence of concrete services such as adjacent services in the composite services. Hence, it is a natural choice to adopt the services selection parameters using a tree graph and encoding method. For the dynamic optimization problem, the selection parameters are encoded based on crossover, mutation, and the immigrant scheme of ISMOGA. ISMOGA is suggested to solve Composite Services Optimization Problem (CSOP) in dynamic environments and to satisfy QoS requirements. CSOP can be embedded in different group communications and collaborative network applications that are based on real-time delivery such as the video conference service and distance learning applications [14], [15].

Information transmitted between the source and the destination needs to be activated and guaranteed. Therefore, QoS classification of real-time delivery is required for multimedia applications, and tree paths have to be constructed [16]. The cost of tree paths should be calculated to evaluate network resources and VMs configurations.

In ISMOGA design, all parameters and functions are related to the composite services. We used several immigrants of memory schemes and their combination into the GA to enhance its searching capacity for the QoS and user's preferences in dynamic environments. When the configuration of topology is changed, new immigrants or valuable information will be stored in the memory that can help guide the search for feasible solutions in the new dynamic environment [17]. In the simulation experiments, the experiments evaluated these ISMOGA in a dynamic environment under different parameters and configurations to find the best solutions. ISMOGA is used as a composite algorithm that is applied to work with composite services to evaluate their performance.

5. Problem Formulation

ISMOGA is applied to the concrete services package for building abstract services. It is used to determine the QoS constraints for cloud customer services [18]. These constraints (attribute values) are related to a composite service, for example, minimum cost, minimal response time, maximal resource availability, and reliability at the same time.

5.1. Series Services Reliability (SSR)

SSR contains a set of independent services (n).

Figure 1: General structure of Series Services

Let us assume the service event S_i has functioned properly $P(S_i)$. $R_i = P(S_i)$, it stands for series services reliability.

$$R_s = P(S_1 \cap S_2 \dots S_n) = P(S_1) * P(S_2) * \dots P(S_n),$$

The product law of reliabilities applies to series services of independent systems as shown in Equation (1), where, R_i – the reliability of service i .

$$R_s(t) = \prod_{i=1}^N R_i(t) \quad (1)$$

5.2. Series Services Availability (SSA)

To compute the availability of independent repair services, we need to apply the product law as shown in Equation (2), where, A_i – the stable-state or temporary availability of service i .

$$A_s(t) = \prod_{i=1}^N A_i(t) \quad (2)$$

$A(s)$ can be calculated by Equation (3), where, $MTTF_i$ – Mean time to failure, $MTTR_i$ – Mean time to repair.

$$A(S) = \prod_{i=1}^n \frac{MTTF_i}{MTTF_i + MTTR_i} \quad (3)$$

5.3. Parallel Services Reliability (PSR)

The complex system consisting of n independent parallel services. The system fails if all n services fail. Services status can be represented as follows.

S_i – service i is working properly, \bar{S}_i – service i is not working properly, S_p – parallel services of n are working properly.

$$P(\bar{S}_p) = P(\bar{S}_1 \cap \bar{S}_2 \dots \cap \bar{S}_n)$$

Therefore:

$$P(\bar{S}_p) = P(\bar{S}_1)P(\bar{S}_2) \dots P(\bar{S}_n)$$

Parallel services are a system that has n independent parallel services.

Figure 2: General structure of Series Services.

Parallel services reliability can be defined as follows.

$$R(t) = 1 - \prod_{i=1}^n (1 - R_i(t)) \quad (4)$$

Parallel services availability as defined in equation (5).

$$A(t) = 1 - \prod_{i=1}^n (1 - A_i(t)) \quad (5)$$

5.4. Series-Parallel Services

Reliability of abstract service $R(A_c)$ has the reliability of each concrete service $R_i(C_s)$. Figure 3 shows Series-Parallel services consist of 2 abstract services and 5 concrete services.

Figure 3: Series-Parallel services

Parallel systems are working if at least one $R_i(C_s)$ of A_{ci} is up as shown in Equation (6).

$$R = [1 - (1 - R_1)^2][1 - (1 - R_1)^3] \quad (6)$$

5.5. Concrete Service Availability

Concrete Service Availability (CSA) is a metric to measure the probability that a service is not available when it is needed to be used. Qualifications of concrete service that must be available:

- Functioning equipment: service is not out of work for fixing or inspections.
- Service is operating under standard conditions: it operates in a trusted environment and at an expected rate.
- Service works when it is needed: it can be launched at any scheduled time.

5.6. Concrete Service Reliability

Concrete Service Reliability (CSR) is the probability rate that a concrete service carries out correctly in specific time duration.

In the cycle life of the correct process, no repair is required and the system service appropriately follows the required performance specifications.

5.7. Concrete Service Failure Rate

Concrete Service Failure Rate (CSFR) is the frequency of concrete service failure per unit time. It is usually denoted by Lambda (λ).

To calculate the reliability of concrete services, the rate for the severity of the concrete service's failure is predicted as the concrete service is fully functional at the initial stage.

The formula of service reliability is calculated for repairable and non-repairable system services respectively as follows.

$$CSFR = \frac{1}{MTBCSF} \quad (7)$$

$$FRCS = \frac{1}{MTTCSF} \quad (8)$$

where, MTBCSF – the mean time between concrete services failure (Non-Repairable), while MTTCSF – the mean time to concrete services failure (Repairable).

5.8. Concrete Service Repair Rate

Concrete Service Repair Rate (CSRR) is the rate successful frequency of repair operations achieved in a failed concrete service per unit time. The CSRR is calculated in (9).

$$CSRR = \frac{1}{MTTFCs} \quad (9)$$

5.9. Mean Time to Concrete Services Failure

Mean Time to Concrete Services Failure (MTTCSF) is the average time before non-repairable CS downtime. Equation (10) computes MTTCSF as follows.

$$MTTCSF = \frac{\text{Total Hours (CS Operation)}}{\text{Total Number (CS Units)}} = \frac{1}{\lambda} \quad (10)$$

5.10. Mean Time between Concrete Services Failure

Mean time between concrete services failure (MTBCSF) is the average time among inherent failures of repairable concrete services.

The MTBCSF can be calculated using equation (11).

$$MTBCSF = \frac{\text{Total Hours (CS Operation)}}{\text{Total Number (CS failures)}} = \frac{1}{\lambda} \quad (11)$$

5.11. Mean Time to Concrete Services Recovery

Mean time to concrete services recovery (MTTCSR) is the average time to fix a failed state of concrete service and back to an operational state. This stage includes time spent on the diagnostic and alert process, and before repair activities.

$$MTTCSR = \frac{\text{Total Hours (CS Maintenance)}}{\text{Total Number (CS Repairs)}} = \frac{1}{\mu} \quad (12)$$

5.12. Mean Time to Concrete Services Detection

Mean time to concrete services detection (MTTCSD) is the average time elapsed between the occurrence of concrete services failure and its detection.

$$MTTCSD = \frac{\text{Total Hours (CS Incident Detection)}}{\text{Total Number (CS Incident)}} \quad (13)$$

5.13. Availability and Reliability calculations

Calculations are calculated for the availability and reliability attributes of concrete service. The failure rate of CS can be calculated interchangeably based on MTBF and MTTF according to the above calculations.

Reliability is exponentially computed for the decay probability function, which depends on the failure rate of the concrete service, as the failure rate may change over the lifecycle of the operational concrete services.

The average time-based quantities such as MTBCSF or MTTCSF can be used to compute Reliability.

The mathematical formula used to calculate MTBCSF is represented in Equation (14).

$$\text{Reliability (t)} = e^{-\lambda t} \quad (14)$$

Availability determines the component's immediate performance during any given time based on the period between its failure and its recovery. Equation (15) can be used to calculate the Availability.

$$\text{Availability (t)} = \frac{MTBCSF}{MTTCSF + MTBCSF} \quad (15)$$

5.14. Web Service Systems

Web Service Systems (WSS) include multi-services linked together as a complex architecture of the system.

The effective availability and reliability of the WSS depend on the specifications of the individual components as network configurations and service redundancy models.

The network configuration can be parallel, sequential, or mixed communications between network components.

Redundancy model service may cause the abortion of internal service components and change the availability of effective service and reliability performance.

5.15. Reliability Block Diagram

Reliability Block Diagram (RBD) can be used to illustrate the interconnection among individual services. Another option, the analytical techniques can also be applied to perform the large calculations of the complex system. RBD illustrates a hybrid system that contains series and parallel service connections among components of the complex systems as shown in Figure 4.

Figure 4: Series and Parallel Service Connections a Hybrid System

The formulae of effective failure rates are used to calculate the availability and reliability of a hybrid system.

The real failure rate associated with the series concrete services (Cs) is defined as the overall failure rates per $S(\lambda_c)$.

$$\lambda(Cs) = \sum_{c=1}^n \lambda_c \quad (16)$$

MTTF is defined in parallel concrete services, as the mutual total of failure rates of each of Cs.

$$MTTCSF = \frac{1}{\lambda_1(Cs)} + \frac{1}{\lambda_2(Cs)} \dots + \frac{1}{\lambda_n(Cs)} \quad (17)$$

In hybrid systems, the CS must first be collected to parallel or series concrete services. Calculations of hybrid components should be reduced for parallel or series configurations.

It is important to note a few caveats regarding these incident metrics and the associated reliability and availability calculations.

Reliability and availability calculations can be understood in relative terms, for example, in different network applications the failure of the same components can be described differently.

In cloud applications, the measurement values may be inconsistent. Therefore, measurement values such as MTTR, MTTF, MTTD, and MTBF have been calculated in experimental results under controlled environments as follows.

- The functionality of QoS characteristics has been optimized. The customer can reduce response time and cost as possible. QoS characteristics are characterized by different preferences of the customer and can be expressed based on the preference weight.
- Resource constraints must be available in the infrastructure of the IT provider. Therefore, the proposed research will select several services based on available resources.
- Web service composition is the main force for developing services, and thus complex services have specific functions divided into different service components.
- Component functions are fulfilled by several candidates for concrete services. Therefore, service providers provide services with the same functionality, but according to changing circumstances, these services could be combined with a set of combination plans for the same functions while the contents differ [19], [20].
- The VM must contain all requirements of service components so that the total requirements of the composite service must match the configuration and capabilities of VM that are implemented by processing units, the capacity of memory cards, network configurations, supporting devices, and any other components.
- Servers and IT resources are required for users and companies to obtain high quality service during peak load times. The peak capacity is often used to evaluate server usage levels, so we have to find the percentage of CPU utilization.

5.16. Virtual Machine Resources Problem

Virtual Machine (VM) in cloud computing has a set of resources R and its attributes A . V_{Rt} represents VM resources V at time t . We consider $A = \{Mrt, Srt, Prt, Urt\}$, and $R = \{r_1, r_2, r_3, \dots, r_i\}$ where, $r_i \in R$. Each resource r_i is defined based on its attributes as follows. V_{Mt} is the VM memory capacity at time t , V_{St} is the storage capacity of VM at time t , V_{Pt} is the VM processing capacity at time t , and V_{Ut} is the VM utilization rate at time t .

We define the fitness function $f(V)$ to evaluate the VM resources (VMR), which has two sections. The first section is an objective function to integrate QoS attributes. The second is an immigrant function that has constrained for optimization problems and selects the individuals obeying constraints and user's preferences to immigrants in the next generation, as calculated by Equation (18).

$$f(V) = \sum_{i=1}^m (w_i * q'_i) - \beta \sum_{j=1}^n (w_j * \Delta q_j) \quad (18)$$

Where, m – the number of QoS attributes, n – the number of QoS constraints, β – a coefficient of an experience rate, w_j and w_i – fitness values and QoS attributes, q'_i – a part of selection

parameters to integrate the QoS attribute values. Δq_j – user preferences or global constraints.

The subtraction in the equation shows the immigrant function based on the survival probability of individuals who satisfy user's preferences.

Web Service Systems (WSS) include multi-services linked together as an architecture of complex systems.

The combination services problem between the abstract nodes and concrete services is represented in the tree graph $G(N, C)$.

$N = \{A_i, c_1, c_2, c_3, \dots, c_j\}$, where $A_i = \{a_1, a_2, a_3, \dots, a_i\}$ is a set abstract service nodes, and $C_j = \{c_1, c_2, c_3, \dots, c_j\}$ is a set of concrete services.

Concrete services have a set of resources $C_i(R_n) = \{r_1, r_2, r_3, \dots, r_n\}$ where, R is the resources of concrete services.

Services cost can be defined as,

$$C(S) = c_1(a_1) + c_2(a_2) + c_3(a_3) + \dots + C_i(a_i). \quad (19)$$

while, cost of resource nodes,

$$C(R_i) = c_1(r_1, r_2, r_n) + c_2(r_1, r_2, r_n) + c_3(r_1, r_2, r_n). \quad (20)$$

where, c_1, c_2, \dots is the total cost of concrete services.

In combination services tree, T is defined as below:

$$T(A_i, C_j) = \{a_i, c_1, c_2, c_3, \dots, c_j\}. \quad (21)$$

ISMOGA optimizes and improves QoS of composition services by minimizing the following objectives i.e.

Definition 1. The total cost of all services nodes (N) along with $C_T(a_i, c_j)$ is equal to the total response time of services $T(a_i, c_i)$.

$$T(N_T(a_i, c_j)) = \sum_{s \in N_T(a_i, c_j)} (T(s)) \quad (22)$$

The total cost of QoS is defined as the total cost of all graph nodes in the composition services as follows.

$$C(N_T(a_i, c_j)) = \sum_{s \in N_T(a_i, c_j)} (C(s)) \quad (23)$$

Availability of the services nodes $A(a_i, c_j)$ is defined as the maximum available of concrete services nodes at any time associated with the abstract node as shown in Equation (24).

$$A(N_T(a_i, c_j)) = \max\{A(s_i), s \in N_T(a_i, c_j)\} \quad (24)$$

The reliability of the services nodes $R(a_i, c_j)$ is defined as the maximum available concrete services nodes at any time associated with the abstract node as defined in Equation (25).

$$R(N_T(r_i, c_j)) = \max\{R(s_i), s \in N_T(r_i, c_j)\} \quad (25)$$

The services selection scheme uses the fitness function to express the required relationships among structure resources of VM based on different types of candidate services as follows.

Series Services refers to activities of services arranged sequentially, Services are executed one by one, so the activity output of one will be used as input to the next service. Figure 5, shows series services are executed $P1 = \{S1, S2, S3\}$. Besides,

there are controls for data flow from one service to the next service as illustrated below.

Figure 5: Series Services of VMs

Services wrap defines a structure in which a hidden services activity is nested into services activity (wrapping). It is used to implement a service that needs to execute another service to complete a special subtask.

Figure 6: Wrapped Services (S3) of VMs

In Figure 6, service S2 is a wrapping service that needs an activity of wrapped service S3 to complete a subtask, and then subtask S3 retires its data to wrapping service, this will be repeated many times as necessitated based on the control of the workflow and tasks needed.

Finally, the data flow will exit from service S2 to the next service (S4). The output of the data flow can be expressed as a longer sequence structure, for example, $P1 = \{S1, [S2, S3], [S2, S3], [S2, S3], S2, S4\}$. In this case, there are three calls to the wrapped service S3, and there are many cycles among the wrapped and wrapping service.

Parallel activities describe a structure formed of a parallel service, included n of activities performed as services parallel and synchronization. The data flow and control continue from the first synchronization point to terminate all tasks of parallel branches as illustrated below.

Figure 7: Parallel Services (S2, S3) of VMs

Figure 7 shows two services S2 and S3 are performed as parallel tasks $P1 = \{S1, [S2, S3], S4\}$, and service S4 is performed after finishing both S2 and S3.

Conditional Choice is a component composed of an exclusive selection with n conditional sections to perform one of these sections and followed by a merge process. In this case, the workflow is supposed into a sequence after calculating the number of loops such as $P1 = \{S1, S2, S4\}$, $P2 = \{S1, S3, S4\}$.

Figure 8 illustrates a combination pattern of conditional choices.

Figure 8: Conditional Services (S3, S4) of VMs

At the workflow level, the service attributes must be aggregated for all workflow deployments as shown in Figure 9.

Figure 9: Composition Services Workflow Mapping

The complex architecture of combination services contains sequential and general flow structures. The general flow structure includes non-sequential patterns such as parallel and conditional paths. Services loop can be transformed into sequences by unfolding known cycles. Figure 10 illustrates the VMs' complex architecture of composition services and resources.

Figure 10: Illustrates the complex architecture of composition services

The matrix representation $M(S_i, C_j)$ is used to illustrate the tree nodes of abstract and concrete services for composition services and calculate the fitness values of candidate services. The tree scheme (T) has four methods to evaluate the fitness values for each service as follows:

$$F(T) = f_1(c_{ij}) + f_2(t_{ij}) + f_3(a_{ij}) + f_4(r_{ij}); S, C \in M(s_i, c_j) \quad (26)$$

The following rules should be applied to get the candidate services.

- The tree service that doesn't satisfy the QoS constraints and users' preferences should be eliminated.
- If there one single service between two candidate services and this service satisfies the QoS constraints, it will be selected automatically.
- Among multiple trees of candidate service, the best service will be selected.
- Satisfy all resources constraints $R_i = \{r_1, r_2, r_3 \dots r_i\}$ of services infrastructure $S_i = \{s_1, s_2, s_3 \dots s_i\}$. Requirements of service components located in VM must be less than VM capacities.
- To build one complex system, all required services should be collected together and ordered by tree services $T(S_i, C_j)$.
- In the final step, we built one-line services instead of multi-distribution services after calculating fitness values for all trees.

The fitness method can be used to evaluate all services nodes components. We assume the cost range is $10 \geq c \geq 1$, the minimum response time is $1 \leq t \leq 10$, the maximum resource

availability is $90 \leq a \leq 100$, and reliability at the same time is $80 \leq r \leq 100$. In this example, if the cost constraint $c=4$, time constraint $t = 5$, resources availability $a = 95$, and resources reliability $r = 85$. Resources constraints of IT infrastructure for VMs are represented as follows, $R = \{r_1, r_2, r_3\}$, where, r_1 – CPUs processing capacity per VM is 32, r_2 – memory capacity per VM is 1024 G, and r_3 – storage capacities per VM is 100 TB.

In all component service paths and their dependencies, various QoS states and constraints are included from abstract service to its concrete services. The tree scheme can illustrate all nodes of services that satisfy users' preferences in the same period.

The proposed algorithms can be applied to sequential and general flow structures. The general flow structure includes non-sequential patterns such as parallel and conditional paths. Loops can be transformed into sequences by unfolding the known number of cycles.

In merged nodes, QoS values, as well as utility values, need to be merged. In parallel merged nodes, since all services in all branches preceding the join are executed, QoS values need to be aggregated based on the properties of specific attributes. For example, the cost and response time for each path are summed, whereas the minimum values are chosen, while for the availability and reliability the maximum values are chosen. At conditional joins, the true conditions of the chosen branch are selected. Figure 11 shows the service candidate graph and all possible paths from the source to the destination services.

Figure 11: The service candidate graph.

Table 1 shows the matrix representation used to represent all path trees of composite services.

The QoS attributes have various aggregation functions per workflow pattern. The QoS has a set of standard functions such as min, max, sum, and product.

The fitness functions for service cost, time, reliability, and availability are defined respectively.

$$f(c) = \sum_{c \in Ti(s, d_i)} P_c(s, d_i) P_c \in P \quad (27)$$

where, $f(c)$ – the total cost for each service in the path tree $T_i(s, d_i)$.

$$f(t) = \sum_{t \in Ti(s, d_i)} P_t(s, d_i) P_t \in P \quad (28)$$

6. Simulation Experimental Results and Analysis

Simulation comparisons were performed on the QoS of composite web services. All experimental results were taken on the same software and hardware to test the studied algorithms. The experiments were executed using the python programming language to determine the efficacy of the web service composition selection.

The experiment analyzed and evaluated the tree paths of combination services and structure resources of an abstract that satisfy users' preferences and QoS constraints using the proposed algorithm (ISMOGA), Standard Genetic Algorithm (GA), and Multi-Objective Genetic Algorithm (MOGA).

The QoS and costumer's constraints are met in composite web services based on abstract services and concrete services satisfying QoS constraints, achieving the resource constraints of the VMs. Figure 15 shows the computation cost in seconds for composite services and one execution path using MOGA and ISMOGA. In both algorithms, the computation cost increases with the task number and the candidate services number. However, the computation cost of the ISMOGA (70 seconds) is less than in the MOGA (95 seconds).

Figure 15: Computation cost of MOGA and ISMOGA algorithms.

Figure 16 shows the relationship between the fitness average and the generation number for MOGA and ISMOGA algorithms using the same number of resource constraints and user preferences.

Figure 16: Fitness values and generation number of MOGA and ISMOGA.

In the experiment, we have implemented both algorithms MOGA and ISMOGA according to their techniques. Resource constraints and user preferences were equivalent for both algorithms, as the experimental parameters were the same, including population size = 100, generation number = 1000, point crossover probability = 0.5, point mutation probability = 0.1. Figure 17 shows the comparison results for minimum execution times based on the number of composite services used ISMOGA to get high-quality visual solutions and perform QoS requirements.

Figure 17: The execution time of the MOGA and ISMOGA

Figure 18 shows the results obtained from the search algorithms based on the number of concrete services to obtain the best and most effective solutions.

Figure 18: Comparison between search algorithms

Figure 19 shows the characteristics and number of the required resources for VMs in a dynamic environment that is changing rapidly. ISMOGA algorithm is more adapted and efficiently based on changed characteristics in the environmental dynamics (ENDY).

Figure 19: MOGA versus ISMOGA in environmental dynamics.

Figure 20 illustrates a comparison of the average fitness values for availability and reliability obtained for MOGA and ISMOGA. The results show the capability of ISMOGA is more efficient as it can be seen that the obtained time value for execution time is small.

Figure 20: Availability and reliability of MOGA and ISMOGA.

Figure 21 shows a comparison of specific cost values obtained for each algorithm between (0-1000) generation intervals. The result of the analysis explains the cost paths of MOGA and ISMOGA that are satisfied with the resource constraints of the VMs and QoS that are the main references for the fitness function.

The experiment results show that applying ISMOGA search method to get the best solutions for composite web services problems is feasible and effective. The experimental results illustrate the best cost of the proposed algorithm = 260 while the cost of MOGA = 320. ISMOGA adapts quickly compared to MOGA and obtains high-quality visual solutions to satisfy QoS requirements. ISMOGA applied to work with DOPs to evaluate their performance and obtain the best solutions. Furthermore, the immigrant scheme was organized in the ISMOGA to improve its searching capacity.

Figure 21: The comparison of cost values in different intervals generation.

Figure 22 shows the result of three types of techniques of genetic algorithm (GA, MOGA, ISMOGA) and their fitness functions. The parameters used in the experiment are population size – 400, crossover probability – 0.7, mutation probability – 0.1, generation – 500, and running times is 50/ms.

Figure 22: The comparison results of three studied algorithms

The experiment result shows that the proposed ISMOGA algorithm more effective than other algorithms by using the immigrant scheme to improve its searching process.

The experiments were implemented to evaluate the total reliability for each service, where the number of VMs=100, the best value of fitness function = 0.979 of the proposed algorithm, and the number of generation = 500. Figure 23 shows the comparison results of the three algorithms and the maximum value of VM reliability. The experiments are implemented to evaluate the solution quality of availability for each service of composite services and structure resources. The best value of fitness function = 9.66 of the proposed algorithm, and the number of generation = 500.

Figure 23: The maximum VM reliability of the proposed algorithm.

Figure 24 shows the comparison results of the genetic algorithms and their maximum value of availability with high quality of services at the path of candidate services.

Figure 24. Maximum availability value of the proposed algorithm.

7. Conclusion

In this study, we have proposed and developed a multi-objective genetic algorithm using the immigrant schemes in selecting search methodology to get the best solutions that meet the requirements of QoS in solving the composite services problems. A multi-objective genetic algorithm has been applied to develop and improve the problem of the web service composition to obtain the best services and recourses that are available in the dynamic environment. The study contribution helps a service provider to find the best solutions based on determining a set of concrete services efficiency and satisfy user's preferences and QoS of concrete services. The Interdependence between concrete services and abstract services is built to improve and provide a function with high quality and characteristics in the service requested by the customer, taking into consideration the available preferences and capabilities. The available resource constraints are a significant part, therefore the best paths of the multicast tree in the network environment were analyzed and determined to achieve the highest levels for all service components available in VMs based on configuration, capabilities, and resources to be compatible with VMs in the cloud environment. The experiments are performed using the fitness function of ISMOGA, which gives indications for selecting a group of desired individuals and excluding other groups that do not achieve the multi-objective and constraints. Experimental results show that the proposed algorithm was one of the best scientific solutions in dealing with complex and NP problems.

ABSTRACT

Vehicle number plate detection and recognition is an integral part of the Intelligent Transport System (ITS) as every vehicle has a number plate as part of its identity. The quantity of vehicles on road is growing in the modern age, so numerous crimes are also increasing day by day. Almost every day the news of missing vehicles and accidents are perceived. Vehicles tracking is often required to investigate all these illegal activities. So, vehicle number plate identification, as well as recognition, is an active field of study. However, vehicle number plate identification has always been a challenging task for some reasons, for example, brightness changes, vehicle shadows, and non-uniform license plate character type, various styles, and environment color effects. In this review work, various state-of-the-art vehicle number plate detection, as well as recognition strategies, have been outlined on how researchers have experimented with these techniques, which methods have been developed or used, what datasets have been focused on, what kinds of characters have been recognized and how much progress have been achieved. Hopefully, for future research, this review would be very useful.

1. Introduction

Vehicle Number Plate Recognition (NPR) or License Plate Recognition (LPR) or Registration Plate Recognition (RPR) is an enhanced computer vision technology that connects vehicles without direct human connection through their number plates [1-3]. Day by day, the number of vehicles on the road is continuing to grow. For this reason, the news spread almost every day about the vehicle being filched from the parking garage or any other place in the city or having an accident and fleeing. To recognize these vehicles [4, 5], authorities should therefore install a number plate detection and recognition device on CCTV at every street corner in every region. This system enhances the police's ability to track illegal activities involving the use of vehicles. NPR systems are effectively used by provincial establishments and manufacturing groups in all facets of safety, inspection, traffic management applications [6, 7].

The number plates vary from country to country. There are some rules and regulations for vehicle number plates. Number plate consists of (1) 2 letters (these refer to the region in the country where the vehicle was first registered) (2) 2 numbers (when it was issued) (3) 3 letters chosen at random. Some basic information about vehicle number plates like dimension, styles, and characters

of number plates fitted after 1st September 2001 is shown in Figure 1.

Figure 1: Vehicle number plate fonts and spacing [8]

Some variations are often seen on the vehicle number plates. The difference between American and European number plates is that American vehicle number plates have more things than identification numbers, sometimes little pictures, different color text but in European vehicle plates are used just for identification. Front number plates must show black characters on a white background and the rear number plate must have black letters on a yellow reflective background [8]. The number plates dimension of

the car and motorcycle in the UK (United Kingdom) is shown in the form of Table 1.

Table 1: Dimension of the vehicle's number plate in UK standard.

Dimension		
Properties	Car	Motorcycle
Character Height	79 mm	64 mm
Character Width	50 mm	44 mm
Character stroke	14 mm	10 mm
Space between characters	11 mm	10 mm
Space between groups	33 mm	30 mm
Space between vertical lines	19 mm	13 mm

For nearly half a century, vehicle number plate detection, as well as recognition, has been a topic of interest. This technique in the field has opened new challenges. In terms of consistency, color, number plate shape, and type of vehicle, the major challenges of vehicle number plate detection as well as recognition are focused on the various categories of features and are related to changing illumination level, the geometry of visualization, and background [9,10]. In Figure 2, typical samples of vehicle number plates [11] are shown.

Figure 2: Samples of vehicle number plate [11]

Number plate recognition procedure is divided into three key functions: Identification of Plate Area, Segmentation of Plate Character, and Recognition of Character [12-16]. In terms of traffic management, traffic optimization, traffic law enforcement, vehicle access control, automated collection of tolls, traffic speed control, automatic parking, monitoring of stolen cars, and tracking of possible acts of terrorism, each of these aspects plays a crucial role [6, 7, 14, 17, 18].

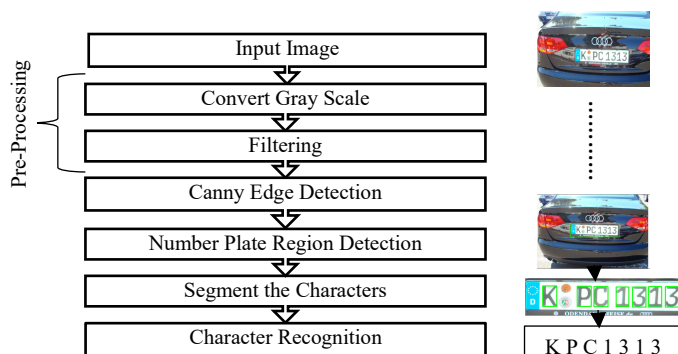

Figure 3: Flow diagram of common number plate detection and recognition method

Figure 3 shows common vehicle number plate detection and recognition method based on the edge detection method. At first, the vehicle registration plate detection as well as the recognition system capture the image using the camera and then apply some

image processing techniques for pre-processing the image such as input image to grayscale image conversion, filtering technique to eliminate noise. Next, to extract the license plate area, apply the canny edge detection technique. After that, apply the appropriate detection method to detect the vehicle registration plate effectively, and apply the segmentation technique to segment the characters of the registration plate. Finally, the appropriate character recognition method is used to recognize each of the characters separately.

Due to the lighting conditions, the noisy image captured, fast-moving vehicles, are always a difficult task in vehicle number plate identification as well as recognition. Several researchers have been working on vehicle number plate recognition and are still working in this field. They have adopted several image processing techniques and presented some of their development strategies for vehicle number plate detection. As much research has been done so far in this paper on vehicle number plate detection as well as recognition and their success behind their proposed method and exactly what caused their proposed method to fail is discussed here. And this paper explores how to resolve their limitations or what more can be achieved in this area in the future.

Vehicle number plate detection studies, as well as recognition techniques, have been categorized into three sections in this review paper: (1) Related Works on Vehicle Number Plate Detection Techniques (2) Related Works on Vehicle Number Plate Recognition Techniques (3) Related Works on Vehicle Number Plate Detection as well as Recognition Techniques.

The residual of the paper is arranged in a structured way. The number plate detection strategies are demonstrated in section 2. Techniques for number plate recognition are discussed in section 3. In section 4, techniques of vehicle number plate detection, as well as recognition, are illustrated. Finally, section 5 states the conclusions.

2. Related Works on Vehicle Number Plate Detection Techniques

Number plate detection (NPD) is a technology that uses certain image features to understand vehicle registration plates to assess location data for vehicles [14,19]. To determine a location going to the next frame, NPD identifies a region of the vehicle number plate with similar structures. The consecutive frame fixes the area of detection in the prior frames with the observed area of the vehicle [20]. During the identification of the registration plate of the vehicle, various difficulties of the surrounding environment were observed. In addition to these, several vehicle number plate considerations are concise in Table 2.

Different researchers have talked about their proposed techniques for identifying vehicle number plates at different times and still a lot of work is being done following their proposed method. Many image processing techniques are existing to detect vehicle number plates such as segmentation, edge detection, color code-based techniques, feature-based techniques, and machine learning techniques. This section discusses different strategies associated with the identification of vehicle number plates. Centered on various methods, the following section is split into several sub-sections.

2.1. Edge Detection

In image processing, it is possible to recognize the edges of the image through different edge detection techniques, such as Sobel, Prewitt, Laplacian, and Canny edge band detectors. The Sobel edge detector effectively transforms a compact, detachable, and numeral valued filter to the image in a horizontal and vertical direction. Prewitt is used in frames to detect vertical and horizontal edges. Hence Sobel and Prewitt are kind of similar. Canny edge detector probably the most effective method for complex edge detection. Below, discussed the previous literature of vehicle number plate detection techniques based on edge detection.

In [22], an algorithm has been suggested for vehicle number plate detection in practical situations by Wazalwar. To define the region of interest (ROI), they used the Euler number of a binary image and for edge detection, they used the Mexican hat operator. They have claimed that a license plate had been successfully identified through their suggested technique and their success rate was about 94-99% and the average accuracy was about 96.17%. Yet there is a situation during their prosperity where they have suffered. The edge detection system fails to properly recognize the edge if the license plate is black.

In [23], a license plate detection system founded on an enhanced Prewitt arithmetic operator has been suggested by Chen under various backgrounds and lighting conditions. The projection method was also carried out horizontally and vertically to change the top and bottom edge areas along the edge to get the vehicle number position. They have achieved 96.75% precision in their proposed technique, and they have stated that their proposed system meets efficiency in real-time.

An innovative technique for vehicle number plate detection using the special technique of edge detection [24] has been introduced by Tejas. They have used the Sobel edge detection technique to obtain accurate boundaries of the number plate in the image. The system scanned the connected component and then fill them with holes. Thereafter, the system searches the rectangular region that is filled with holes which is probably the size of the license plate and then extracts it. Their proposed system is based on the Internet of Things (IoT). Therefore, online databases have been developed and regularly updated. They have also estimated that the accuracy of their acquisition is around 96.842%. In Figure 4, their suggested technique is shown.

2.2. Morphological Operation

Morphological Operations in image processing attempts to remove these imperfections by considering the image's shape and structure. To reduce noise or to brighten the frame, morphological

operations are essentially applied to grayscale images. Morphological operations are referred to as a blend of erosion, dilation, and basic set-theoretical functions, such as a binary image supplement [25]. The corresponding study on morphological operation-based vehicle number plate detection techniques has been discussed below.

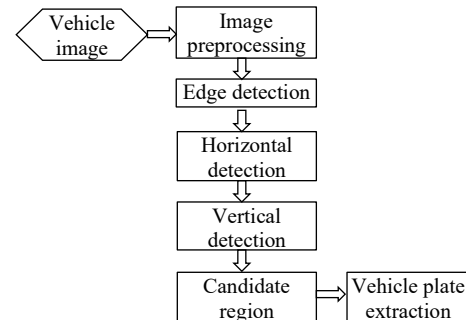

Figure 4: Block diagram of the proposed method [24]

In [26], an existing system used for license plate location on a Raspberry Pi has been improved by the Yepez. Their improved morphological algorithm that reduces computational complexity is based on morphological operations. The strength of this strategy is that the emerging LPR algorithm can operate with the computer as well as low processing power on portable devices. They have also claimed that their enhanced algorithm can detect license plates effectively and have achieved a high precision is about 98.45%. In Figure 5, the flowchart of their proposed method is shown.

2.3. Convolutional Neural Networks (CNNs)

A convolutional neural network (CNN) based framework for the detection of vehicle number plate was proposed by the authors in [27]. They have enhanced the existing blurred and obscure image method. They believed that their suggested method effectively detects the number plate of the vehicle under various lighting conditions. The accuracy obtained by their proposed method is around 100%.

2.4. Machine Learning (ML) based Approaches

Machine Learning (ML) likewise means that by providing a collection of training data, the machine is trained to do something in image processing. Machine learning has models/architectures, functions of loss, and many methods that can be used to decide which will provide better processing of images. For image enhancement, this approach is commonly applied. The corresponding work of machine learning-based vehicle number plate detection techniques is given below.

In [5], a new technique to detect a vehicle authorization plate has been developed in the Miyata study. The license plate detection technique detects only the edge vertical parts and the candidate license plates that use the contours acquired by dilation and erosion processing and area fill processing. The SVM (Support Vector Machine) has applied to decide whether a license plate is a candidate region or not, and eventually recognizes the location of the license plate. They have claimed that the suggested method efficiently detects license plates and achieved the rate of detection is 90%.

In [28], an innovative method has been presented for detecting and locating a vehicle's license plate in color images by Yaseen. AdaBoost, a multi-boosting model based on HOG features, is part of the development process. They have claimed that the accuracy achieved by their proposed method is around 89.66%. Figure 6 displays the flow chart of their suggested system.

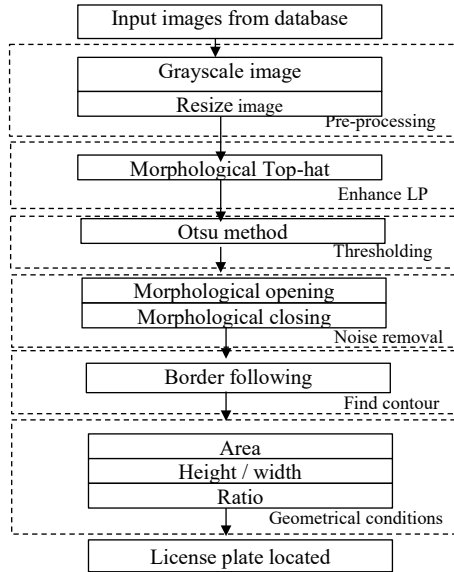

Figure 5: Flowchart of the proposed method [26].

In [29], a vehicle registration plate detection method in the natural image by AdaBoost using the Modified Census Transform (MCT) feature has been suggested by Ban. There are too many noises in the natural image, so detecting the number plate in natural images is too difficult. MCT features, which are robust to illumination change, and AdaBoost for the feature selection to overcome this restriction. They have also reported that the high detection rate achieved by the proposed technique is about 98.7%.

In [30], a systematic style for vehicle registration plate detection applying boosting and part-based models was proposed by Molina-Moreno, which is an algorithm for boosting. They used two datasets and stated that better performance on these datasets was obtained 97.52% accuracy by their proposed method. With several algorithms, they have also compared their proposed method.

In [31], a novel vehicle number plate detection system has been suggested to improve identification in low lights and over corrosive environments by Babbar. For the extraction of license plates, they used CCA (Connected Component Analysis) and Ratio Analysis (RA). Some OCR strategies have also been used, for example, LR+RF, SVC+KNN, Extra Trees, SVC (Linear, Poly, Rbf, Linear.svc). They stated that the car localization achieved by the developed system is 92.7% and the segmented characters' accuracy is about 97.1%.

In [32], a KNN (K-nearest Neighbor) machine learning system for automatic vehicle license plate detection was developed by Akshay Iepcha. The KNN classifier has been used according to the aspects of the license to retrieve the registration plate from the image. They have also stated that a license plate is correctly identified through their suggested method and achieved an accuracy higher than 90%.

Table 3 provides an overview of the strategies for detecting the vehicle number plate. This table has been sorted based on the year and accuracy.

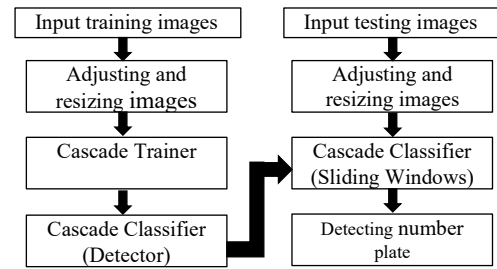

Figure 6: Flowchart of the proposed ANPD system [28].

3. Related Works on Vehicle Number Plate Recognition Techniques

Vehicle Automatic Number Plate Recognition (ANPR) is a technology applied for the observation as well as recognition of vehicle number plate characters from static and moving vehicle images [14, 28, 32, 33]. Due to its effect on the rapid development of traffic monitoring and surveillance [15, 22, 34, 35], vehicle number plate recognition has become a key research field in recent years. For the identification of number plates, several methods are used, such as machine learning, neural networks, BAM (Bidirectional Associative Memories) [35]. Various researchers have given their useful ideas on their proposed vehicle number plate recognition method at various times. In this review paper, various vehicle number plate recognition techniques have been explored. Vehicle number plate recognition techniques have been categorized into some subsections based on distinct approaches in the following section.

3.1. Neural Network (NN) based Approaches

Image recognition algorithms in neural networks (NN) can recognize anything, from text to images, audio files, and videos. Neural networks are an interlinked set of neurons or perceptron's called nodes. Each node uses a single input data, generally a single pixel of the image, and uses a simple calculation called an activation function which produces results and each neuron has a numerical score that determines its outcome

1. Artificial Neural Networks (ANNs)

In [15], a high-performance-based system for vehicle number plate recognition has been introduced by Türkyılmaz. They have applied edge-based image processing techniques for registration plate detection and have also used a three-layer feedforward artificial neural network for vehicle number plate character recognition using a learning algorithm for back-propagation. The feedforward ANN model for three layers is shown in Figure 7. The input layer receives information from the external environment and transmits it to the nodes (processing units) of the hidden layer without any modification. Network outputs are calculated by processing information in hidden layers and output layers. The most well-known back-propagation learning algorithms are used efficiently at the training stage of this ANN. The authors have verified that the number plate has been successfully identified and recognized by their developed system and their performance rate

Table 3: Summary of the vehicle number plate detection techniques

First Author & Year	Detection Methods	Datasets	Accuracy	Advantages	Limitations	Future Opportunities
Eswar, 2020 [27]	Convolution Neural Network (CNN)	Private dataset	100%	Able to detect number plate at different lighting conditions and processing time will be less.		
Molina-Moreno, 2019 [30]	Scale-adaptive deformable part-based boosting algorithm	Caltech, LPR and MMR Database	97.52%		The proposed system, due to the presence of noise, lack of lighting, and blurring of remote license plates, is not high enough in many realistic scenarios.	To improve the process of segmentation, morphological structures can be assumed.
Yaseen, 2019 [28]	AdaBoost based HOG features	North Iraq Vehicle Images (NI-VI) dataset,	89.66%	The dataset must cover all real-life vehicle conditions likely to start, such as weather conditions, size, color, and license plates.		This dataset can be further used for Automatic Number Plate Recognition systems.
Yepez, 2018 [26]	Morphological operations	MediaLab LPR database	98.45%	Able to work on both a computer and low power portable device.		Any other image processing technique can be applied for further improvement.
Babbar, 2018 [31]	CCA, Ratio analysis, LR+RF, SVC+KNN, Extra Trees, SVC (Linear, Poly, Rbf, Linear.svc)	Vehicles at IIIT institution	Detection rate 92.7%, accuracy 97.1%	The system is successfully detecting number plates from skewed angles.		Perhaps this system can be improved by locating the reversed vehicle number plate in the event of an accident and warning the nearest hospital and policing station of the accident, thus saving lives.
Akshay Iepcha, 2018 [32]	KNN Classifier	Their own dataset with videos	Higher than 95%	Improved performance is 11%.		
Tejas, 2017 [24]	Sobel edge detector	Their own dataset	96.842%	Proposed system makes easier to update database.		Genetic algorithm can be applied for better performance and web application can be integrated.
Miyata, 2016 [5]	Support Vector Machine (SVM)	Their own dataset with 100 images.	90%		The detection rate is significantly influenced by the luminosity of the body of the vehicle license plate.	The detection rate can be increased by improving brightness or other features.
Chen, 2012 [23]	Prewitt operator for edge detection		96.75%	Suggested system performs in real-time.		Different edge detection method can be used.

Ban, 2012 [29]	AdaBoost based on Modified Census Transform (MCT) features	Their own dataset with 3373 LP images	98.7%		Proposed method is failed to detect the numbers, which have different width/height ratio when the training stage.	The shortcomings can be improved in the future.
Wazalwar, 2011 [22]	Mexican hat operator for edge detection	Medialab LPR Database	96.17%		Black license plate cannot detect the edge properly.	Motion analysis can be applied to overcome failure.

Figure 7: Three-layer feedforward ANN model [15]

II. Convolutional Neural Networks (CNNs)

CNN is familiar to describe the characters that appear in the segmented License plates (LPs). CNN consists of, as seen in Figure 8, a set of layers of conv (Convolution), pooling, and fully connected (FC) layers [36].

In [11], a system for automatic number plate recognition applying convolutional neural networks (CNN) centered on self-synthesized features was proposed by Mondal. The self-synthesized feature of CNN can recognize the states of the vehicle from the number plate. They have confirmed that their system is robust and effective with accurate identification of the license plate of the vehicle from the images above 90%.

Figure 9: Vehicle number plate recognition results using dataset [37].

In [37], a set of vehicle number plate recognition techniques has suggested by Yang. They have first introduced a contour

reconstruction method with edge-detection to accurately detect the number plates and then used a zero-one-alternation technique to effectively remove the misleading top and bottom borders around plates to allow more precise character segmentation on plates. Subsequently, for character recognition, a convolutional neural network (CNN) was applied. Furthermore, the SIFT (Scale Invariant Feature Transform) feature has been used in CNN for successful training. SIFT is a feature detection algorithm and it helps to locate the local features in an image. Finally, a two-phase verification approach has been implemented, the first phase is a statistical filter in the LPD phase to effectively remove the wrong plates and the second phase is shortening the system pipeline, which increases the LPDR system's performance. They have confirmed that the intended method essentially recognizes the vehicle number plate in real time and achieved a precision rate is about 84.3%. Figure 9 displays the recognition results of the proposed system.

Figure 8: The design of CNN for character recognition [36].

In [38], an interference occurrence on CNN classifiers in the License Plate Recognition Systems (LPR) was introduced in the study of Qian, which adds pre-arranged alarms to definite parts of license plate images, pretending to have indeed formed spots. They have used the genetic algorithm technique to enhance the difficult issues. During vehicle number plate identification, spots that are not usually accessible to humans will be at great risk at any point. They have argued that they were able to identify the number plate character effectively despite getting several spots and their performance rate is 93%.

In [39], a framework for the identification of vehicle license plates on urban roads focused on vehicle tracking and data integration was implemented by Zhu. An object detection framework is trained, centered on a plate detector, to detect each vehicle's license plate from the video series. The convolutional neural networks (CNN) have been applied for vehicle registration plate recognition from the video sequences. Besides, the continuous frames have combined recognition effects to achieve the result. The proposed LPR system layout focusing on vehicle tracking and outcome incorporation is shown in Figure 10. They claimed that under the real urban road climate, their license plate detection accuracy and recall were 82.5% and 89% respectively.

Figure 10: Structure of the LPR system centered on vehicle tracking and result integration [39].

In [40], the authors presented a system of image de-noise supportive of defining the license plate of the vehicle. They also combined a new de-noising and rectification approach conducted by CNN that focuses on jointly solving both problems. They argued that their proposed approach effectively recovers the image issues of the low-quality license plate and identifies the character successfully. They claimed that their proposed method achieves 93.08% accuracy for detecting the license plate.

III. Generative Adversarial Networks (GANs)

In [41], a new method of making text images of high-resolution license plates has been introduced by Gupta where the style and textual content of the images are parametrically represented. To acquire the conditional generation of photo-realistic images, the proposed system combines text to image recovery techniques with Progressive Growing of Generative Adversarial Networks (PGGANs). They have used the American license plate dataset for the proposed system and achieved higher accuracy to recognize the registration plate characters.

In [42], a method of registration plate recognition for speeding vehicles using a motion camera was proposed by Wang, implying whether something is feasible to create synthetic training data using GAN to enhance identification precision. They used a Deep Convolutional Neural Network (DCNN) accompanied by a long-term short-term memory (LSTM), Bidirectional Recurrent Neural Network (BRNN), which performs the learning function and sequence labeling. They reported that the recognition accuracy achieved by the proposed system was 89.4% for moving cars on demanding test datasets.

In [43], a method for registration plate recognition in the natural environment has been suggested by Zhang. Their suggested method contains a customized model of Cycle GAN for license plate image generation. They have employed a 2D attention plate recognizer with an Xception-based CNN encoder which can reliably and efficiently differentiate license plates with different designs. Four datasets were also used by them to assess the efficiency of their proposed framework and achieved an accuracy higher than 80%.

IV. Recurrent Neural Networks (RNNs)

In [44], a combined ConvNet-RNN model was developed by Cheang to identify legitimate captured registration plate images. To develop feature extraction, a Convolutional Neural Network (ConvNet) is included. For computation, a Recurrent Neural Network (RNN) has been applied. They tackled this problem by promoting the whole image as a contribution to ConvNet, sliding windows could not access the whole image context. They have confirmed that the combined model achieved over 76% accuracy in recognizing the license plate characters in their dataset, with a per-character accuracy of 95.1%.

3.2. Computer Vision (CV)

In [45], an algorithm based on computer vision technology for automatic vehicle license plate recognition has been introduced by Akila. The suggested system addresses various lighting conditions by capturing the image file collected at different times. They used Optical Character Recognition (OCR) to retrieve the numbers from the number plate. They have tested their proposed system for different data with different characteristics of number plates, such as black, inverted color, bold or stylish pattern. Recursive subdivisions have been used to extract character image features. They have stated that the proposed system was successfully identical, extracted, and segmented by the license plate, and achieved a higher, good, and acceptable rate.

3.3. YOLO (You Only Look Once)

YOLO is an actual algorithm for object detection, among the most effective and significant object detection algorithms, which integrates several pioneering ideas in computer vision from the scientific community [46]. All of the previous algorithms for object detection use regions to locate the object within the image. YOLO greatly differs from region-based algorithms. The bounding boxes and the class probabilities for these boxes are predicted by a single convolutional network in YOLO. YOLO is faster (it can deal with 45 frames per second) than other algorithms for object detection. But the YOLO algorithm is limited by the fact that it manages with small objects within the image.

In [47], a robust and efficient YOLO object detector-based ALPR system has been implemented by Laroca. They have used an inverted License Plates (LPs) system for the segmentation and identification of characters applying basic techniques for data improvement. Both Fast-YOLO and YOLOv2 models were evaluated at this point to be able to handle simpler (i.e., SSIG) and more realistic (i.e., UFPR-ALPR) data. For simpler situations, Fast-YOLO should be able to correctly detect vehicles and their LPs in a much shorter time. The resulting ALPR process has also obtained crucial results in two datasets. They reported that their system achieved a recognition rate of 93.53%.

In [48], an efficient and effective YOLO object detector-based layout-independent Automatic License Plate Recognition (ALPR) framework has been suggested by Laroca that includes a coherent technique for detection and layout classification of license plate (LP). In their proposed ALPR system, they performed experiments with the Fast-YOLOv2 and Fast-YOLOv3 models. In the validation set, Fast-YOLOv2 obtained slightly better results than its successor. This is since YOLOv3 and FastYOLOv3 have

relatively high performance on small objects but comparatively worse performance on medium and larger size objects. Eight public datasets were used by them and many data augmentation techniques were used on the datasets. They have confirmed that an overall identification rate of 96.8% on the datasets was reached by the proposed method.

In [49], an inventive vehicle license plate location system using the latest YOLO-L model and pre-identification plate was developed by Min. The proposed model modifies two parts to discover the area of the license plate precisely. The k-means++ clustering algorithm was first used to choose the appropriate size and amount of the candidate boxes for a plate. Next, the YOLOv2 network model and depth were amended. To separate license plates from related items, they also used a plate pre-identification algorithm. They have claimed that precision of 98.86% and a recall of 98.86% were achieved by the proposed method.

In [50], a global vehicle license plate recognition scheme has been suggested by Henry. The intended method was founded on the YOLOv3 networks. The suggested system consists of three key steps: 1) identification of License Plate (LP), 2) recognition of unified characters, and 3) detection of global LP layouts. They used their Korean dataset to test their success and used the dataset of the other four countries. They have confirmed that the proposed ALPR method consumes an average of around 42ms per image to extract the number of LPs and achieves an accuracy of up to 90%.

3.4. Deep Learning (DL) based Approaches

In [51], a system for vehicle license plate recognition in complex environments using a deep learning approach was suggested by Weihong. First, more sophisticated algorithms for key issues such as skewing of the license plate, image noise, and blurring of license plate were implemented. Then the deep learning algorithms were listed as algorithms for direct detection and indirect detection, and the detection and recognition of license plates and algorithms were analyzed. Besides, contrasts were made between the variations in data sets, workstations (special computers that provide higher performance, graphics, memory space, and multitasking capabilities), precision, and time complexity of various license plate recognition systems. Finally, the existing public datasets of license plates were compared and illustrated as per the set of images, the resolution, and the sophistication of the area. They reported that their model achieved a segmentation rate of 82.6% and recognition precision of 87.3%.

In [52], an innovative deep learning-based vehicle registration plate recognition approach for general road surveillance cameras is presented by Elihos. In the character detection and recognition process, the suggested free segmentation license plate recognition technique employs deep learning object detection techniques. They used their private dataset containing 2000 images captured on a highway, which were tested. They also stated that the overall accuracy of the proposed achievement is 73.3%.

In [53], an SSD (Single Shot Detector) based natural environment registration plate recognition system has been suggested by Yao. The proposed LPR-SSD network is composed of two networks centered on SSDs. The proposed method is subdivided into two sections. The first part consists of locating and classifying the plate detection, and the second part is to locate and

identify character recognition. They reported that the LPR-SSD achieved a greater acceleration in testing and the accuracy of identification and classification of license plate location exceeded 98.3% and the accuracy rate of character recognition exceeded 99.1%.

3.5. Image Processing Techniques

I. Edge-based Approach

In [54], a system for automatic license plate recognition founded on integrated edge-based Connected Component Analysis (CCA) techniques was proposed by Arafat where license plate identification, segmentation, and recognition of different shapes have focused. They ensured that better character segmentation was accomplished by the proposed approach and that 96.5%, 95.6%, and 94.4% were correct for identification, segmentation, and recognition respectively.

II. Gradient Segmentation

In [55], a system for vehicle license plate tracking through gradient-based segmentation was developed by Kumar. Gradient-based segmentation adjusts the lighting level of the image to ascertain the position of the license plate. The proposed approach filters the region of interest using the Hue, Saturation, and Value (HSV). They also ensured that the proposed system accurately tracks the vehicle's license plate to recognize the registration plate characters and achieved the precision is about 94%.

III. Optical Character Recognition (OCR)

In [56], an automated number plate recognition system manipulating image processing techniques was introduced by Kashyap. To recognize the characters on the license plate, Optical Character Recognition (OCR) converted the lettering on the number plate image to text. They have achieved accuracy is about 82.6%.

In [57], an effective process for automatic license plate recognition was intended by Pechiammal. The proposed method consists of three portions: segmentation of characters, identification of optical characters, and matching of models. They have demonstrated that the suggested method effectively extracts character from the plate and 85% is the extraction rate.

In [58], an innovative vehicle number plate recognition method using OCR and template matching strategies for the Pakistani language has been suggested by Rehman. Several real-time images from different formats of number plates used in Pakistan were evaluated by the proposed ANPR system. They stated that for law enforcement agencies and private organizations to enhance home security, the ANPR model has both time and money-saving profit. They reported that 93 % accuracy of their proposed ANPR approach was achieved. This system can be further expanded to identify the number plate of the crashed vehicle in an accident and warn the nearest hospital and police station about the accident, thereby protecting the number plate of the accident.

3.6. Feature Extraction Technique

In [59], an innovative method was intended for the framework of vehicle registration plate recognition based on compressive sensing techniques using reduction of dimensionality and

extraction of features by Joki'c. To extract the features, they used the Support Vector Machine (SVM). They announced that the proposed method has achieved an average accuracy is about 98.81%.

3.7. K-means Clustering-based Approach

In [36], an efficient deep learning-based approach to recognition plate for vehicles, including appropriate optimal K-means clustering segmentation and Convolutional Neural Network (CNN), was implemented in the research of Pustokhina. Optimal K-means clustering is used for segmenting the license plate and a Convolutional Neural network is used for recognizing the license plate characters. The Bernsen Algorithms (IBA) and the Connected Component Analysis (CCA) models were used to classify and locate the license plates. They have reported that the maximum accuracy obtained by the proposed Optimal K-Means with Convolutional Neural Network (OKM-CNN) system on the datasets is about 98.1%.

3.8. Genetic Algorithm (GA) based Approach

In [60], introduced the latest approach to image-processing algorithms and the optimized genetic algorithm (GA) of the Neutrosophic Set (NS) by Yousif. Certain techniques including

edge detection and morphological localization were initially introduced. Besides, they also used a new method using a new approach to optimize the (NS) operations for extracting the most salient features (GA). Furthermore, the clustering algorithm k-means was introduced for the segmentation of (LP) characters. Finally, the Connected Components Labeling Analysis (CCLA) algorithm has been used to identify the associated pixel domains and the labeling accuracy obtained by the efficiency of the suggested new method was 96.67% for Arabic-Egyptian (LP) and 94.27% for English (LP) and that the computations in both databases had an estimated completion time of approximately 0.996 seconds. Language is the most important factor to recognize characters. Each researcher uses different methods for the different languages for which the recognition rate varies. But English is the common language, and a very good number of techniques for English language recognition compared to other languages. Although the Arabic-Egyptian language is harder to recognize than English, the reason for the higher recognition rate is the image resolution.

Table 4 provides an overview of the techniques used to recognize vehicle number plates. This table has been sorted based on the year and accuracy.

Table 4: Summary of the proposed vehicle license plate recognition methods.

First Author & Year	Recognition Methods	Recognition Character	Datasets	Accuracy	Advantages	Limitations	Future Opportunities
Pustokhina, 2020 [36]	OKM-CNN, Improved Bernsen Algorithm (IBA), CCA	English	Stanford Cars, FZU Cars and HumAIn.	98.1%	Performs in real time.		Multilingual LPs can be increased to recognize the efficiency of the OKM-CNN model.
Yousif, 2020 [60]	Neutrosophic set (NS) based Genetic Algorithm (GA), K-means Clustering, CCLA, edge detection	Arabic – Egyptian, English	Private dataset, Media Lab benchmark LP and AOLP benchmark LP dataset	96.67% for Egyptian and 94.27% for English	Easily recognizes Arabic or Egyptian characters as well as English characters.		Optimization techniques such as particle swarm, ant colony, chicken swarm, and fuzzy techniques can be added.
Arafat, 2020 [54]	Connected component analysis, integrated edge based technique	English	Malaysian LPs	94.4%	For real-time applications, this technique is useful.		In the future, it is possible to recognize font similarity issues in LP characters using the DL architecture.
Rehman, 2020 [58]	OCR, Template Matching	Pakistani	Private Dataset contains 900 images	93%		The identification rate of their proposed scheme is lower for unclear plates, blurring and non-standard vehicle number plates.	The accuracy can be improved, and this system can be further expanded to identify the number plate of the crashed vehicle

Henry, 2020 [50]	YOLOv3 Networks	Korean and English	KarPlate, AOLP, Caltech Cars, Medialab LPR, University of Zagreb	Higher than 90%	The proposed scheme is applicable to the license plate for vehicles in several countries.		
Weihong, 2020 [51]	Deep learning approaches	English and Chinese	Caltech Car, English LP, Chinese LP, UFPR-ALPR	87.3%			An algorithm with an image deblurring and plate correction can be implemented, or the license plate detection rate can be increased.
Zhang, 2020 [43]	CycleGAN model, Xception-based CNN encoder	Chinese	CCPD, AOLP, PKUDData, CLPD	More than 80%		Images with extreme blur or occlusion are unable to recognize.	A transformer-like decoder may be explored to accelerate training speed.
Yao, 2019 [53]	SSD based approach	Chinese	Their own dataset contains 16 types of license plates	99.1%	Efficiency of the proposed system is real timing.		
Joki'c, 2019 [59]	Compressive Sensing Technique, SVM	English	Character Image set in CV toolbox for matlab	98.81%	The proposed system has great performance in classification.		
Laroca, 2019 [48]	Fast-YOLOv2 and Fast-YOLOv3 models.	Chinese and English	Caltech Cars, EnglishLP, UCSD-Stills, ChineseLP, AOLP, OpenALPR-EU, SSIG-SegPlate, UFPR-ALPR	96.8%	Proposed system achieved an impressive trade-off between accuracy and speed.		Further optimization the system can be used a new CNN architecture.
Kumar, 2019 [55]	Gradient based Segmentation, Edge detection techniques	English	Their own dataset contains 78 images.	94.87%	This system to be helpful for the security of the vehicles.	This system could not extract the license plate with a yellow base.	This technique can be applied for any type of character segmentation and recognition.
Lee, 2019 [40]	Image De-noising, Rectification, CNN	English	AOLP-RP and VTLPs dataset	93.08%		Some cases LPR makes a mistake in detection and classification.	Adjacent context can be added in the future.
Zhu, 2019 [39]	Convolutional Neural Networks (CNN)	Chinese	Their own dataset, contains 19020 images	82.5%	This method is feasible and accurate in real time.		Performance can be further improved.

Elihos, 2019 [52]	Deep learning techniques	English	Private dataset	73.3%		In weak character signals, the proposed system cannot detect properly.	It is possible to apply adequate methods of deep learning-based object classification.
Akila, 2019 [45]	Optical Character Recognition (OCR), Recursive sub-divisions	English	Private dataset	Achieved higher rates.	This type of technology involves identifying vehicles that are unknown.	There is no classification between the customer and the visitor in this system.	In the future, to identify the visitor, a separate scanner will be installed.
Laroca, 2018 [47]	Fast-YOLO, YOLOv2, and CNN	English	SSIG and UFPR-ALPR.	SSIG: 93.53%, UFPR: 78.33%		For certain real-world ALPR applications, this outcome is still not acceptable.	In the future, character segmentation and recognitions techniques can be improved.
Gupta, 2018 [41]	Progressive Growing of Generative Adversarial Networks (PGGANs)	English	American license plate dataset	More than 90%		Quality of synthesized images suffers when there are too few samples of a given style in the training data.	This system can be used in more complex scene text synthesis.
Kashyap, 2018 [56]	Image processing techniques, OCR	English		82.6%			Multi-level genetic algorithms can be added for further improvement.
Türkyılmaz, 2017 [15]	Edge-based method and three-layer feedforward ANN	English	Their own database contains 357 images	97%	The developed system performs in real-time.		Advance image processing techniques can be applied.
Cheang, 2017 [44]	CNN and RNN (Recurrent Neural Network),	English	Their own Malaysian VLP dataset contains 2713 images	95.1%	This system performs in real time.		Substituting for long-term short-term memory (LSTM) for the CNN module would improve performance.
Mondal, 2017 [11]	CNN based self-synthesized feature learning algorithm	English	Their own dataset contains 800 images	90%	This system runs on automation.		System performance can be done in real-time.
Wang, 2017 [42]	GAN (Generative Adversarial Networks), DCNN, BRNN (bidirectional recurrent neural network), LSTM (long short-term memory)	Chinese	Dataset1 contains 203774 images and dataset2 contains 45139 images	89.4%	The significance of GAN is magnified when real annotated data is limited.		Accuracy can be improved in the future.

Pechiamal, 2017 [57]	Image Processing Techniques	English		85%	Low processing time.		An influential ANPR framework can use used to manage multi-style plates.
----------------------	-----------------------------	---------	--	-----	----------------------	--	--

4. Related Works on Vehicle Number Plate Detection and Recognition Techniques

In [61], a new system for detecting and recognizing the Indian vehicle number plate has been suggested by Varma that can compete with noisy, low-light, cross-angled, non-standard font number plates. This work uses many image processing techniques in the pre-processing stage, such as morphological transformation, Gaussian smoothing, and Gaussian thresholding. They have used the K-nearest neighbor (KNN) approach for recognizing the character. They have stated that their proposed system achieved 98.02% accuracy for vehicle number plate detection and 96.22% accuracy for character recognition.

In [62], Automatic Number Plate Detection (ANPD) and Automatic Number Plate Recognition (ANPR) systems were intended for the detection and recognition of vehicle number plates in the research of Yaseen. A new realistic vehicle image dataset for three cities, called North Iraq-Vehicle Images (NI-VI), has been presented (Duhok, Erbil, and Sulaimani). Three types of images, such as rotated, scaled, and translated, are included in the collection of data.

In [63], the latest approach to identify and recognize the license plate centered on a hybrid feature extraction model and BPNN,

which is adaptable in poor lighting and complex contexts, was introduced by Xie. They reported that the accuracy achieved by the proposed technique is 97.7% and the processing time is 46.1ms.

In [64], a full unregulated scenario ALPR method has been proposed and implemented a new Convolutional Neural Networks (CNN) to detect as well as recognize the number plate of the vehicle in an input image. To identify the character, they used OCR technology. They have reported that an average accuracy of more than 80% was reached by the proposed method.

A systematic technique was developed in [65] for the identification, segmentation, and recognition of characters within the license plate. To extract the characters from the number plate, they utilized Hough Transform and horizontal projection. They ensured that more than 90% higher accuracy was reached by the proposed system.

In [66], a Bangla license plate recognition system based on Convolutional Neural Networks was suggested by Shaifur Rahman, which could be used for various purposes, such as roadside assistance, vehicle license status identification. Six CNN layers and a fully connected layer were used by the authors for training. They have reported that 89% testing precision was achieved by the proposed Bangla license plate recognition system (BLPRS).

Table 5: Summary of the proposed vehicle number plate detection and recognition techniques.

First Author & Year	Detection & Recognition Methods	Recognition Character	Datasets	Accuracy	Advantages	Limitations	Future Opportunities
Alam, 2021 [68]	CNN and Deep Learning	Bengali	VLPR vehicle dataset	98.2%	This system is used for smart cities.		The system can be used for LP in other languages.
Varma, 2020 [61]	Morphological transformation, Gaussian smoothing, Gaussian thresholding, and KNN	Indian	Private dataset	Detection: 98.02% and Recognition: 96.22%		When font size of LP is smaller, the suggested method gave poor prediction.	In the future Convolutional Neural Network can be integrated that incorporates both detection and recognition into a single structure.
Onim, 2020 [69]	YOLOv4, CNN, Tesseract (OCR engine)	Bengali	Private dataset	90.50%		When it is under shade or under direct sunlight, their proposed system fails to detect VLP.	To reduce the effects of blurry VLP and by deploying preprocessing, to overcome the deterrents of OCR.
Yaseen, 2019 [62]	ANPD and ANPR technologies.	Arabic	North Iraq (NI-VI) dataset	-----	Provides a realistic dataset.	The proposed data set is connected to only north Iraq vehicle license plates.	In future, the research for the entire country of Iraq can be strengthened.

Xie, 2018 [63]	Feature extraction model and BPNN	Chinese	Private dataset	97.7%	This system to be helpful for real time applications.		With RFID devices and Bluetooth devices, this work can be enhanced to better precision of recognition.
Hossen, 2018 [67]	Horizontal & Vertical projections, Back-propagation feed-forward neural networks	Bangla	Private dataset	90.5%	Proposed method is very effective for different viewpoints, illumination conditions, and small distances.		In the future, accuracy can be improved.
Shaifur Rahman, 2018 [66]	Convolutional Neural Networks (CNN)	Bangla	Their own dataset	89%		For smaller memory and computational power, the proposed system faced some limitations.	With a higher number of function maps and more layers, the proposed framework can be augmented.
Silva, 2018 [64]	CNN, OCR	English	AOLP Road Patrol, SSIG, OpenALP R, CD-HARD	Higher than 80%.			This research can be extended to detect motorcycle LPs.
Prabhakar, 2014 [65]	Hough Transform, Horizontal Projection	English	Private dataset	94%	This system effectively reduces the computation time.		In the future, the system can be developed at a low cost in real-time.

In [67], a novel method for detecting the Bangla license plate was proposed by Hossen. Firstly, the location of vehicles is determined. Next, compare the RGB intensity of the plate with the vehicle's license and material properties to localize the license plate area. Thereafter, they have separated horizontal projection-based registration using the required threshold value. After that, using vertical projection of the same threshold value, the characters and the digits are also separated. Finally, using the back-propagation feed-forward neural networks, the characters and digits have been established. Authors have reported that 93.89%, 98.22%, and 92.77% respectively are the success rate of the license plate identification, segmentation, and recognition process. In Figure 11, the proposed method is shown.

In [68], a method using Convolutional Neural Network (CNN) and Deep Learning strategies to identify and recognize vehicle number plates in the Bengali language has been suggested by Alam. A super-resolution technique has been used with the CNN in the recognition portion to reconstruct the pixel quality of the input image. Each number plate character is segmented using a bounding box technique. 700 vehicles were appointed to test the experiment outcomes. They reported that in the validation set, CNN gained 98.2% accuracy and obtained 98.1% accuracy in the

evaluation set and the error rate was 1.8%. Their proposed system can be connected to a cloud-based system where all registered vehicle numbers will be stored.

Figure 11: Overview of the proposed method by Hossen [67]

In [69], a prototype of YOLOv4 object detection has been implemented in which the Convolutional Neural Network (CNN) is trained and configured to detect the vehicle's Bengali license plate and to recognize characters from the detected license plates using Tesseract (OCR engine). They reported that the model of license plate detection is trained at 90.50 % to mean average accuracy (mAP) and recall of 0.86 during training.

An overview of the vehicle number plate detection as well as recognition techniques is shown in Table 5. This table has been sorted based on the year and accuracy.

The existing methods for the identification and recognition of vehicle license plates have been classified based on accuracy that is shown in Figure 12.

5. Conclusion

This study paper presents a concise description of the vehicle number plate detection as well as recognition techniques used for effective traffic monitoring and observation of the reliability of the methods. In the construction of a smart transport network, vehicle number plate detection, as well as a recognition system, plays an important role. Although identification of vehicle number plates has always been a difficult proposition for certain reasons including changes in lighting, glare, non-uniform type of license plate, different styles, and color effects in the environment. Recognitions may also use some image processing techniques in conjunction with neural networks to identify the number plate characters, moving distance images, numbering schemes, angled or side-view images. In this study, the methods of vehicle number

plate detection and recognition have been classified based on accuracy. In the future, the preference is to use high-resolution cameras with an improved number of frames for better performance and effective license plate recognition. The classification section can be further improved with the complexity, speed, and chronological order. This study includes a comprehensive evaluation of the progress and future patterns in the identification and recognition of recent vehicle number plates which could be of value to researchers interested in such development.

Conflict of Interest

There is no conflict of interest reported between the authors.

Individual-Based Model

ABSTRACT

On the 11th of March 2020, the World Health Organization (WHO) declared COVID-19 as a pandemic. Part of controlling measures of the pandemic is to understand the disease's trajectories. There are several possible interventions that can prevent and control its spread. Determining an optimal strategy is critical for policymakers to understand the impact of different scenarios. Many modelers are using agent-based simulations to virtually examine the efficiency of these scenarios. This paper aims to review published papers that discussed Agent-based simulation (ABS) for modelling the COVID-19 pandemic. Major databases were searched for published articles in 2020 from top-ranking journals. Ten published papers were carefully chosen, and their findings were summarized and discussed. Among the methods used, three ABS models were shared as open source. Major findings included mask-wearing and working/studying from home as the optimal strategies, whereas airport screening is insufficient, and vertical isolation is similar to 'doing nothing' scenarios. Finally, one paper discussed the gaps in ABS and proposed a call of actions to the scientific community and guidelines to responsibly improve the ABS modelling's quality. This paper can contribute to understanding the current landscape of the COVID-19 pandemic simulation models and their limitations. It is proposed to access selected open-sourced agent-based models to evaluate, utilize, customize or learn from, to help conduct more accurate simulations.

1. Introduction

The city of Wuhan witnessed a viral outbreak for the first time in December 2019. Since then, the virus was classified as a zoonotic coronavirus, belonging to the same family of the Severe Acute Respiratory Syndrome (SARS) coronavirus and the Middle East Respiratory Syndrome (MERS) coronavirus. The novel virus was later named SARS-CoV-2. By February 2020, 33,738 infections were reported in China with 811 deaths. On the 30th of January 2020, The World Health Organization (WHO) confirmed the outbreak as a Public Health Emergency of International Concern. On the 11th of March, the same organization declared COVID-19 as a pandemic [1].

COVID-19 has brought many challenges to humanity, including a demand on novel medical treatments, social policies and economic initiatives. The fast response from the scientific community included dedicating studies from two perspectives to deal with the pandemic: researches focusing on treatment and diagnostic tools, and another dealing with the viral spread

forecasting models [2]. While tight social distancing measures have proven effective in slowing down the viral spread; it was expected that relaxing some of these constraints will result in a second wave of spread [3]. Computational models provide quantitative support to public health teams and policy makers' in their readiness [4]. One of the most useful insights provided by computational model simulations is its ability to virtually explain natural phenomena, which are either not possible to simulate in a real-world, or too costly to be simulated. These simulations can support decision-makers in studying the current plans' efficiency and assist them in developing necessary policies and strategies to limit and control the COVID-19 pandemic [5].

The fast-paced growth of computer processing power allowed the utilization of Agent-Based Models (ABMs) to widely build simulation models for outbreaks [6]. Although experts are building many models to simulate and forecast the infection's trajectories, they do not cover the sophisticated behavioral and social aspects of societies that are exposed to this outbreak [7]. In this research, a survey was conducted on several published papers that used ABM to simulate infectious diseases outbreaks in different scenarios and environments. This review aims to understand the

*Corresponding Author: Abdulla M. Alsharhan, UAE, +971568284998, alsharhan@outlook.com

various uses and limitations of the ABS in building diseases outbreak models.

2. Literature review

2.1. Modelling pandemics

To better understand how a pandemic grows and how human intuition fails, it is first essential to understand the concept of exponential growth (1). It describes how quantities increase over time. In the early days of a pandemic, the growth rate looks like a linear growth, until the window of action had passed. This was particularly true with COVID-19 (Figure 1).

$$X_t = X_0 (1 + R)^t \quad (1)$$

Moreover, another feature of the growth of the positive cases was that the numbers were time-latent. This means that the positive cases are not identified until infected individuals had already been sick for several days and have likely infected other individuals [8]. Therefore, humanity realized the importance of finding new ways to help understand trajectories of pandemics and implement necessary policies to limit and prevent outbreaks such as COVID-19.

Figure 1: Growth of COVID-19 cases in the world in 2020 [1].

Modelling pandemics are rooted in traditions that go back to the 1920s, when mathematical equations were applied to simulate and model the distribution of the disease in populations, including positive cases, recovered cases and fatality rates. While these mathematical-derived approaches helped experts to understand the threshold, nature and herd immunity of plagues; it did not explain social and behavioral factors such as an individual's behavioral response towards public policies, measures, or the impact of mixed social contact on spreading trajectories [7].

2.2. Agent-based Models (ABMs)

In the early 1990s, the agent-based simulation was known as a third way of doing science. The field has substantially transformed since and found its way to the primary science field. Moreover, many ABS frameworks have been developed, such as RePast, AnyLogic and NetLogo. In addition, the open database of ABS models allowed swift and decisive prototyping of model developments [9]. For this paper, we can define the ABM as a computational simulation model, where agents are behaving independently without an external force. The agents' actions are usually a response to the situation they are exposed to during the process of the simulation [10]. Unlike other simulation models, ABMs are described as a simpler one. This type of models do not

use a complicated set of rules or advanced architectures. Nevertheless, they can generate a variety of complicated patterns (behaviors) based on the modelling attributes caused by its simple agent interaction [11].

2.3. Gaps in Agent-Based Models

While mathematical concepts can be concisely defined and described, the same cannot be said of simulation models. Describing early ABMs was challenging to write or understand. No one knew where to locate the different types of information. As a result, the descriptions were often incomplete, and reproducing the model was ultimately impossible [12].

Although many signs of progress were being made in modelling pandemics through agent-based simulations, whenever a new pandemic occurs, similar modelling issues repeatedly arise and require precise attention. These issues include: (1) predicting sophisticated results when the vital data are not available nor reliable (2) reusing the model in a different setting that it was not designed for, and (3) not carefully maintaining good standards, practices or procedures, either for a race to academic recognition or for an immediate response to political pressure [7]. In contrast, [11] proposed a standard format for describing ABMs, known as the "Overview, Design, Details" concept (ODD). ODD was one of the initiatives to counter reoccurring challenges faced, in what has been known as "replication crisis". ODD was developed to make it easier to write, read, implement and replicate ABM. It can include mathematical and short algorithms and is structured into seven steps, as shown in Figure 2. These steps are grouped into three categories, Overview, Design and Details.

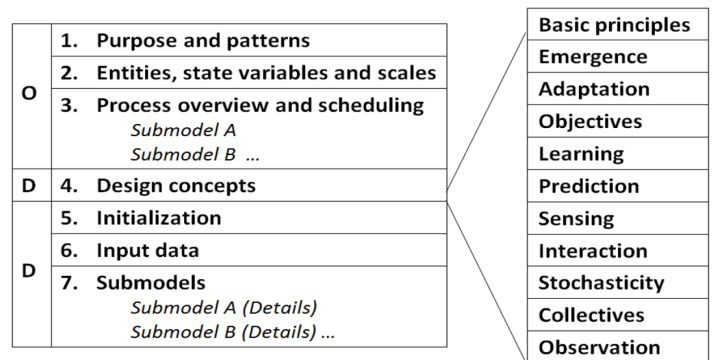

Figure 2: Overview, Design, Details (ODD) concept

3. Methods

3.1. Methodological approach

Document analysis is one of the effective and efficient ways to start the collection of data on a certain topic. Published articles can supply recent and broad data coverage [13]. Search Engines can facilitate faster data analysis. For this research, the critical survey approach was chosen to conduct a primary research, to understand the various uses and limitations of ABS, in building diseases outbreak models.

3.2. Data Collection Plan

Major databases were searched including ScienceDirect, Google Scholar and Crossref for ("Agent-based simulation") OR

("Agent-based Model") OR ("Individual-Based Model") AND ("COVID-19"). Since the focus was COVID-19, and the pandemic only started spreading in early 2020; the time frame was set for all published journal articles in 2020 up to the 19th of October 2020. The search was conducted without language restrictions; finally, all non-mathematical computing models articles were excluded.

3.3. Quality of papers

The focus subject and the time frame of the surveyed papers are relatively new; therefore, high citations was not a good indicator. Alternatively, Scimago Journal & Country Rank ranking (SJR) of [14] was used. Most of the examined papers are ranked between Q1 & Q3. Afterwards, if a paper was not published in a journal yet, the authors' credibility were examined via the ORCID database [15] to check if they have previously published in high ranked journals.

Table 1: Quality assessment checklist

#	Question
1	Is the paper contained in a high ranked journal?
2	Is the paper cited by more than 5?
3	Have the Authors published before in a high-ranking journal?
4	Is the paper providing clear purpose, method and findings?

The papers' quality was evaluated against the quality assessment checklist (Table 1). Each answer has a value, and three different values determine the answer to each question. Questions answered with 'Yes' have been assigned with a value of (1), questions answered with 'No' have been assigned with a value of (0), while questions partly answered have been assigned with a value of (0.5). All papers that scored above 60% were included in the analysis (Table 2).

Table 2: Quality assessment result

Source	Q1	Q2	Q3	Q4	Total	%
R01	1	1	1	1	4	100%
R02	1	1	1	1	4	100%
R03	1	1	1	1	4	100%
R04	0	0.5	1	1	2.5	63%
R05	0.5	0.5	1	1	3	75%
R06	1	1	1	0.5	3.5	88%
R07	1	1	1	1	4	100%
R08	1	0	1	1	3	75%
R09	1	1	1	1	4	100%
R10	1	0.5	1	1	3.5	88%

3.4. Selection of papers

Ten journal articles that matched the research criteria were identified. Table 3 shows each study along with the journal's name, ranking, model used, and its availability. The following table (Table 3) shows the main qualified articles for the further analysis.

Table 3: Names of authors, source and journal and their SJR Quartiles rank

N o.	Journal Name	SJR Quar tiles	Model Availability	Country
R 01	Chaos, Solitons and Fractals	Q1	https://bit.ly/COVID19_ABSsystem	Brazil

4. Results

After analyzing the main contribution of each article, the following are the main identified themes of the studies.

4.1. Agent-Based model of health and economic effect simulation

The authors of [2] pointed out that it is a challenge for decision and policy makers with only limited studies available on the pandemic.. This paper proposed an ABM simulating the viral and economic impact of COVID-19 in a closed environment. The results can be widely used by decision and policy makers to evaluate the effectiveness of different social policies in a real-life scenario.

The proposed ABM is simulating a closed society living in a shared limited environment. The community consists of individuals and groups of families, businesses and a government. Each agent is interacting with each other. The given characterization by the model is supposed to emulate the character of a community.

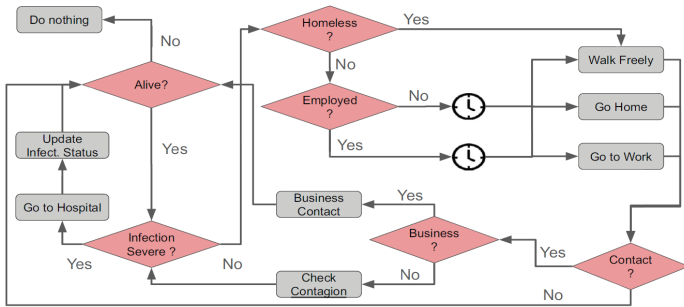

Figure 3: Agent activity cycle by [2].

The paper of [2] studied seven different scenarios using variable social inputs. The findings revealed that a lockdown or a semi-lockdown was the best-forecasted scenario to save lives, slow down viral spreading rates and lessen infection and fatality rates. Moreover, since the complete isolation was not practical, a 50 per cent lockdown scenario with social distance and mask usage was the best policy to save lives. On the other hand, the vertical isolation was ineffective (only persons below 18 years of age and seniors stay at home) was like a 'doing nothing' scenario. These results proved that COVID-19-ABS modelling was able to effectively generate social scenarios, matching several similar studies [2].

Although applying ultimate measures against the pandemic is successfully limiting fatality rates and hospitalizations, it does not mean societies are saved. Without herd immunity as well, a second wave is likely to take place when restrictions are lifted, and rules on taking protective measures are relaxed. In these scenarios, it is vital to analysis different containment strategies to limit the probabilities of other waves, and at the same time, balancing health and economic objectives.

4.2. Agent-based simulation using mobility data with demographic data

In another study [3] focus was made on preventing second waves of the pandemic, by simulating the impact of testing, contact tracing and staying at home. The research used an estimation of population communication patterns between residences to create a detailed ABM. The research used detailed data on transportation, social activities and demographics, and generated a network that coded the patterns of contact for 85,000 agents in an area, for six months. The agents were used to simulate different census locations in the Boston area in the United States. This research followed the same methodology used by [4] in their paper "Measurability of the epidemic reproduction number in data-driven contact networks data-driven contact networks".

The generated network was defined by a proposed multilayer network, forming the basis of social interventions on three layers, namely the school layer, workplace and community layer and house household layer, as displayed in Figure 3.

The estimated intervention between the two agents in the workplace and community layer is calculated from the data by calculating the probability of a mutual meeting between two individuals in a particular place (for example, at a food court or a shop) and using the time spent in the same place as the contributing factor.

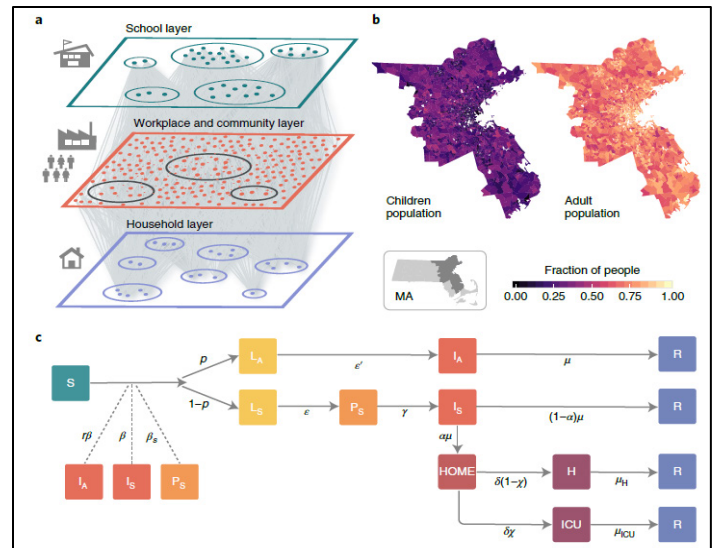

Figure 4: Model component as described by [3] "Susceptible (S), latent asymptomatic (LA), latent symptomatic (LS), presymptomatic (PS), infectious asymptomatic (IA), infectious symptomatic (IS), hospitalized (H), hospitalized in intensive care (ICU) and recovered (R) individuals" [4].

In [4], the author found that the best intervention policies to limit and control a second wave is by imposing a period of strict social distancing, followed by a healthy level of testing. In addition, an effective way of undergoing contact-tracing and home quarantine can keep the pandemic within the limit of the public health care systems in Boston, with the possibility of opening up the economy. While the herd immunity is absent, the finding states that a response system based on testing enforcements and contact-tracing can have a significant role in limiting and relaxing the restriction rules.

4.3. Agent-based simulation in the educational context

Just like the previous papers, [16] aimed their efforts to limit the impact of the second COVID-19 epidemic wave, but within the education context, specifically in UK schools. The research used an ABM called "Covasim". This model was developed in the United States and calibrated to the UK's outbreak parameters. This paper seems to agree with [3]'s findings on the role of large-scale testing, and effective contact-tracing, followed by effective isolation of infected individuals.

However, the research of [17], which also conducted their simulation in the education sector, had additional useful insights. Although both previous papers by [16] and [3] concluded the importance of wide-scale testing, they might have neglected another critical factor. The authors of [17] had pointed out the issue of testing accuracy, and how it is a critical factor that needs to be swiftly addressed. Moreover, the authors also discussed three significant and expected findings that will impact the education sector: (1) Large classes will be significantly risky with increasing infection rates, (2) students should strictly hold-off all sorts of contact with other individuals, and (3) teachers need to be ready for extended students' absence mainly because of being held in quarantine.

4.4. Agent-Based simulation built on pedestrian dynamics

The authors of [6] are suggesting another Agent-Based simulation based on pedestrian dynamics. This paper analyzed how pedestrians behave in open areas in conditions with viral spreading, such as with COVID-19. This evaluation was done to gather useful insights about exposure time, and the effectiveness of social distancing measures, as stated by the German government (1:5m), at “an infection rate of 2%”.

The paper provided a different scenario of pedestrian dynamics in realistic situations while focusing on contagious diseases. The simulation was based on ABM works including “A Mathematical model for the behavior of pedestrians” (1991), “Simulating dynamical features of escape panic” (200), “Self-organizing pedestrian movement” (2001) and “Simulation of pedestrian crowds in normal and evacuation situations” (2002).

The simulation conducted a pedestrian scenario in an ideally sized German supermarket covering 4,800 square meters (80 x 60 meters), including shelves and counters as shown in Figure 5. There were 34 destinations identified as “point of interest” with a set of agents being defined as “infected”.

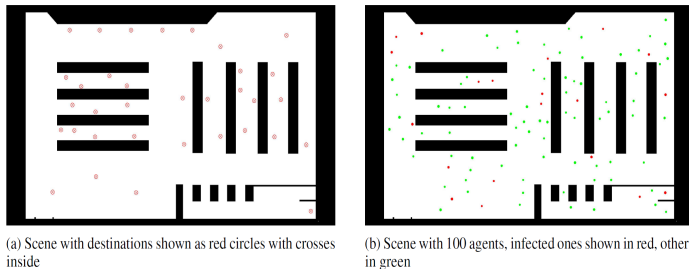

Figure 5: Supermarket layout with walking spaces in white and obstacles in black

The experiment conducted using ABS revealed promising and valuable results for policy makers. The experiment assumed that if the infection rate was 2%, a minimum distance of 1:5 m can be kept if the density is not exceeding one individual for every 16 square meters. The proposed model can be a foundation to better assess the risks in public places within the circumstances of contagious diseases [6].

4.5. Spatio-temporal Agent-Based simulation

The study of [5] investigated the impact of different closure scenarios to control and limit the COVID-19's spread, including schools, educational institutes and the workplace, in addition to social distancing practices in the city of Urmia, Iran. In this paper, the COVID-19 outbreak was simulated with an ABM using a described set of behaviors in a defined environment. The SEIRD model (Susceptible Infectious Recovered Deceased Model) was used to mimic the infection of a human agent. Then, an all-controlling plan was applied to the model.

The attribute of the ABM's environment cells was defined based on the spatial data. The related value was defined based on the spital data layers, as shown in Figure 6.

The simulation results indicated that closure of schools and educational institutes (for 50 days between the 21st of February – the 10th of May 2020) decreased the infection rate by an average of 4.94 per cent weekly and a total of 49 per cent. While working from home at 30 & 70 per cent of Urmia city's population (from

the 21st of February 2020 – the 10th of May 2020) decreased the infection rate by 3.30 & 5.25 per cent weekly and 32.98 & 52.48 per cent in total. Consequently, applying social distancing (from the 27th of March 2020 at 30 & 70 per cent of Urmia city's population), led to a decrease in the infection rate at 5.24 & 10.07 per cent weekly, in addition to 31.46 & 60.44 per cent in total. The main finding recommended applying social distancing to the majority of the population. The paper claimed their novelty was in the model itself, but the model's source code was not provided or shared.

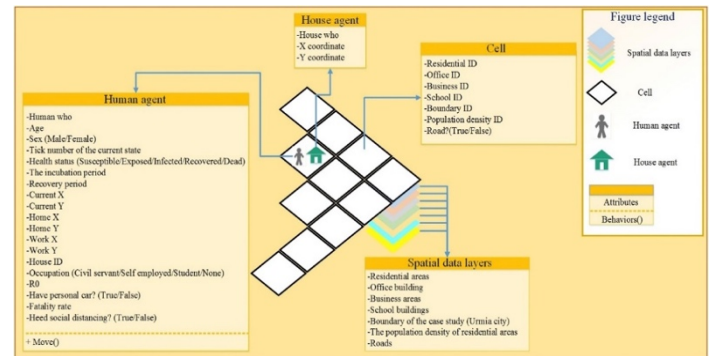

Figure 6: The elements of the Spatio-temporal ABM and their details

4.6. Simulating COVID-19 in facilities

The paper of [11] presented an ABM to evaluate the transmission risks in building environments. The paper tested several scenarios to evaluate and validate the proposed model. The model has been built as an iterative scheme consisting of a Pseudo-code. It was adopted and modified from the work of Professor Hiroki Sayama.

The paper provided the code lines which was considered as simple and can be coded efficiently. According to the study, the model showed useful and promising results that may help decision-makers to determine optimal strategies to reduce infection rates inside facilities and closed environments. The entire process of the model's operation is summarized in Figure 7.

4.7. Simulation of COVID-19 in the construction sector's context

The author of [18] examined another vital sector that little is known about. The study focused on the outbreak of COVID-19 among construction workers using an ABM. The paper's aim was no different from that of other papers, which was examining different intervention strategies. However, there was probable novelty in examining the pandemic's spread in the context of the construction environment. The approach used was classifying the risk of activities for the workers between low, medium and high, followed by simulation of the spread in a construction project. The result of the simulation recommended a reduction in workforce in construction projects between 30 to 90 per cent. However, it was mentioned that a limitation of the analysis might result in the oversimplification of the realistic condition. Nevertheless, the finding of the study can be used as a basis to simulate the potential of second waves after relaxing the social distancing restrictions in regions that have heavy construction works.

Algorithm 1. Pseudo-code for the COVID-19 transmission risk model		
1. Input: $A, B, l_{in}, u_{in}, l_{cm}, u_{cm}, [L_x, U_x, L_y, U_y], \alpha, maxiter, R, S, k=1$

4.8. Simulation accuracy in a responsible manner

Within the context of numerous simulations available and under the pressure of policies makers, [7] presented a paper proposing guidelines, urging the scientific community to follow, so they can handle the transparency and speediness of their findings in a responsible manner.

While many experts have provided sound simulations and prediction of the COVID-19 trajectories; their papers might not cover the complete sophisticated behavioral and social parameters.

Therefore, [7] called for urgent steps to improve the quality of ABMs. The first proposed step was to examine previous ABMs of COVID-19 and explore their potentials, identify gaps, and suggest counter measures. The counter measures would aid in the rapid demand of immediate responses, which is a critical step to avoid collective mistakes. The second suggestion was to consider the pressure between modelling efforts and policy makers, and develop a better understanding of the challenges which aroused from the over expectation of the emerged knowledge, due to misinterpreting the science of modelling. Finally, measures to address these gaps and improve the relationship between the sciences and public policies was suggested. These included a call for a wide-scale cooperation between the public and academic stakeholders, where knowledge, models and data can be exchanged and shared.

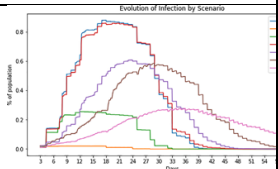

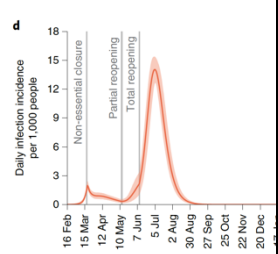

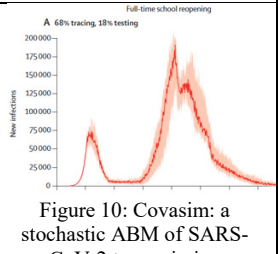

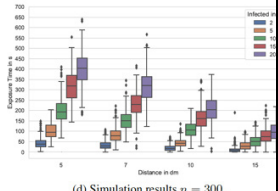

The call to action by [7] can be summarized into two major actions. First was a call to modelers to maintain high standards when building ABMs. The second was for institutional agencies who own useful data that can help calibrate and inform COVID-19 models, to engage with trusted academic associations to make this data available for the rest of the scholars.

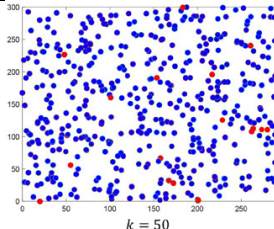

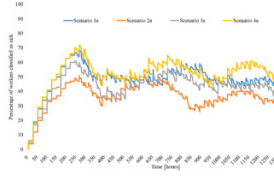

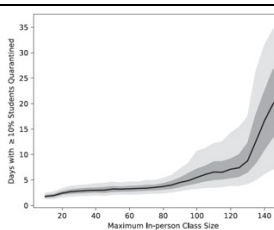

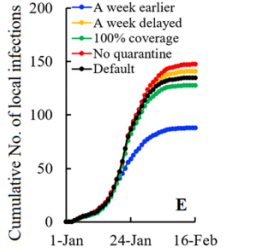

Moreover, the paper recommended to follow three best practices that are already well known among agent-based modelers: (1) building models based on open sources such as MASON and NETLOG, (2) following standing documenting protocols, (3) using long-lasting online content storage tools such as ComSES, to ensure the model is fully documented prior to submission. The paper urged scholar modelers to follow these guidelines, which are very critical during this exceptional times, to enhance their credibility.

4.9. Summary

The following Table 4, summarizes all the examined papers, including article code (N), the main purpose, method used with a model screenshot, the main findings and country (C) of the experiment. The summary excludes the results of [7]. As it is proposing ABM simulation documentation guidelines for the scientific community to follow. However, it has been included for its high importance and relevance to the overall survey.

Table 4: Summary of the analyzed papers

N	Purpose	Method / Model screenshot	Main Finding	C
R01	To simulate health and economic effects of social distancing interventions	 Figure 8: COVID-ABS: a new SEIR ABM	"A useful tool to assist politicians and health authorities to plan their actions against the COVID-19" [2].	Brazil
R02	To simulate the impact of testing, contact tracing and household quarantine on second waves of COVID-19	 Figure 9: R, version 3.4.4	"A response system based on enhanced testing and contact tracing can have a major role in relaxing social-distancing interventions in the absence of herd immunity against Covid-19" [3].	USA

5. Discussion

This paper examined ten research reports adapting ABMs to simulate the impact of COVID-19. Paper [11] presented an ABM to assess the transmission risk in building environments. However, this model was not the only one. [2] also proposed a new Agent-based simulation with promising results. The presented ABS model was not only simulating the transmission risks, but it also emulated the economic impact of businesses and the government. At the same time, an SEIR ABM simulating pandemic outbreaks

with the help of a society of agents called COVID-ABS was presented.

Furthermore, other researchers tried to combine more than one tool. In [5], the author used Spatio-temporal simulation to present the impact of various pandemic preventing strategies, including closures, social distancing, working and studying from home in Urmia, Iran. Other researchers also examined these strategies in Boston, United States. In [3], the author combined more than one instrument. In order to build a detailed ABS simulating a second wave; anonymized, geolocalized mobility data were integrated with census and demographic data. On the other hand, In [6] the author tried to approach pandemic controlling strategies from a different perspective. They focused on examining data on pedestrians behavior and collective time of exposure to evaluate the efficiency of social distancing measures within COVID-19's context.

The aims of the remaining researches were not in developing the model itself, but to use existing ones to support decision-makers in identifying the right intervention strategies. Their novelty was the context of the simulation. In [19], the author presented and analyzed different preventing strategy in Shenzhen. In comparison, [16] conducted a simulation to determine an optimal strategy in the education sector. Likewise, [17] also examined different strategies and measures in the education sector, but their focus was university environments. In [18], the author has moved to a different sector, which is the construction sector. In [18], the author attempted to study the pandemic's impact on construction workers and the best way to lower the infection rate. Alternatively, [7] presented a paper proposing guidelines to ensure transparency and speediness of modelers' findings being made available, are done responsibly.

Most papers used ABMs in their methods except [7], which method and approach were not clear or defined. Generally, the findings of the proposed models were promising and have some useful insights.

The authors of [5] suggest future research to be conducted in a different region that has not been evaluated yet, using different parameters and attributes.

Among the surveyed papers, two significant findings related to widely shared beliefs were proven wrong: The paper of [19] found out that airport screening was not very useful. Forty-six per cent of infected cases were not detected during airport screenings due to several reasons. Part of the failure was due to (1) the sensitivity of the entry and exit screening, (2) asymptomatic cases, and (3) the incubation period, while [2] found that vertical isolation policies promoted by some countries like Brazil and United States was similar to ‘doing nothing’ scenarios. In contrast, [19] reported that working and studying from home and mask-wearing were found to be the most effective policies. [2] seem to reach the same conclusions but in a more realistic manner. Their finding focused on combining wearing of masks and 50 per cent lockdown with social distancing. However, [16] and [3] have added wide-scaled testing as an additional layer of intervention policy. Although nation-wide testing might be theoretically useful, it does not take into consideration the social and behavioral aspect of individuals in addition to their economic situation, where testing is not free in some regions. In addition, there are the issues of testing accuracy,

as pointed out by [17] and the detectability rate as mentioned by [19].

Figure 17: Most discussed subjects based on keywords

6. Limitation and Future work

Many noteworthy articles were missed due to the limited knowledge of different keywords and synonyms used by scholars. Figure 17 shows different keywords commonly used by the examined papers. Moreover, many scholars use arXiv (arXiv.org) e-Print archives as a swift free distribution service with open access. However, papers published in these databases are by invitations only, and not peer reviewed. Therefore, it is not recognized by Scimago's Journal & Country Rank ranking.

7. Conclusion

This paper examined the different discussions on the COVID-19 pandemic's simulations that used ABMs. It was found that agent-based simulation for COVID-19 was used in a variety of contexts, including schools, universities, workplaces, facilities and construction. Methods used varied from simple ones consisting of a few lines of code, to sophisticated models combining mobility data with demographic data or Spatio-temporal data, or from different perspectives such as ABS based on pedestrian dynamics. The main findings of this analysis was in line with works of literature, where mask-wearing and social distancing are among the best strategies, and against some common believes, airport screening and vertical isolation were less effective. The main limitation and future suggestions are on improving the quality of papers by following modelling guidelines proposed by ODD, validating the test accuracy, and considering the behavioral and social attributes of individuals in different cultures and regions.

Outbreaks are usually very sophisticated phenomena, and no one specific model can be applied to all cities of the world [5]. The different parameters do not only impact the infection rates, but they

also vary from one place to another. These parameters include but are not limited to culture differences, literacy, awareness, interactions, transportation, the urban context, population density, job diversity, age variations, gender, number of employees, number of students and people with private transportation means. These only few of the parameters that impact the way the outbreak spreads in different regions. The papers recommended that similar simulations be conducted in a different part of the world using different parameters and different controlling and preventing strategies.

Acknowledgment

This study would not be possible without the guidance of Professor Dr Piyush Maheshwari. The study was a part of a project done at the British University in Dubai. The authors declare no conflicts of interest.

Transformers

Distributed Solar Photovoltaic

Total Ownership Cost

ABSTRACT

To this extent, the delineation of techno-economic evaluations for transformers becomes more intricate through a lens of Distributed Solar Photovoltaic (DSPV) market in South Africa. Essentially, the transformer price and loss evaluation techniques should be tailored for calculating the Total Ownership Cost (TOC) of transformers facilitating decentralized energy systems. In South Africa, the traditional coal power generation and renewables operate concurrently under liberalized energy markets but have distinct operational requirements and therefore have distinct methods for evaluating their generating states, service loss costs and TOC. As a result, their techno-economic evaluations should be different. In this work, new formulae have been developed to contemplate on a comprehensive technique for calculating the transformer prices and losses necessitated to estimate the cost of service losses and TOC for DSPV transformers. These formulae are based on experimental studies undertaken on a fleet of DSPV transformers ranging from 1.25 to 250MVA. In order to substantiate these new formulae, 4 case studies have been presented. The calculated losses and associated cost results against the pragmatic values from the case studies yield an error of estimation of less than 1% and 2% respectively in all cases. Further, these results are used to calculate the cost of losses and TOC using a methodology that has been proposed in previous work exclusively for power producers who are proprietors of DSPV generation systems.

1. Introduction

Transformers make up some of the fundamental power-consuming equipment in the Distributed Solar Photovoltaic (DSPV) systems. The use of transformers has enabled the renewable energy market to grow steadily, with the transformer market expected to increase annually by approximately 16% between 2019 and 2020 [1]. The increased attention by the government to broaden investments in renewable energy resources to satisfy environmental and sustainable objectives is the main driver of this market growth [2]-[5].

The cost-effective measures derived from the choice of enhanced energy efficiency criterion at the time of installation and commissioning of new transformers or replacement of existing units can culminate in a considerable amount of losses decreasing and some benefits for DSPV systems. Contemporary energy-efficient transformers are designed to operate at minimum total losses viz. no-load loss, load loss and auxiliary loss. Transformers

manufactures have modernised the manufacturing procedures and new type of optimised core material with thinner laminations [6], [7] to bestow cost-productive and energy-efficient transformers to utility owners such as the Independent Power Producers (IPP's). Substantially, they reduce power consumption and therefore reduce energy generation and the resultant greenhouse gas (GHG) emissions. Therefore, as renewable energy power systems investment keeps on growing, IPP's are to a larger and larger degree fascinated in installing energy-efficient transformers in their power networks.

The initial purchase price of energy-efficient transformers is relatively high; however, they consume less power during their intended service life in comparison to low-efficiency transformers. The choice regarding buying cheap but high loss transformer or a more expensive, with low loss transformer is mainly a lucrative one. The clarification for picking out one transformer over another should be founded on the initial purchase price plus the operational cost experienced over its intended service lifetime [8], [9], and [10]. A habitual procedure for evaluating the service lifetime cost

*Corresponding Author: Bonginkosi Allen Thango, thangotech@gmail.com

of operation, and consequently the best purchase decision for transformers, is established on a service lifetime loss evaluation procedure that gives the ensuing Total Ownership ($TOC - ZAR$) of Transformers. It is pivotal to appreciate that each power utility's operation conditions, to the extent that the transformers service lifetime loss evaluation methods are concerned, could be not similar. Even within one country, different power utilities may have unique operation objectives and financial goals. For instance, service lifetime loss evaluation procedure for DSPV systems engrosses a thorough knowledge of the generation profile based on the availability of solar irradiation and estimation of the incurred losses as a result of this effect and other factors including possible additional losses due to harmonic currents.

On the other hand, for wind plants, a comprehensive understanding of the factors like wind output speed and generation hours per annum are essential [11] – [12]. In the mainstream, the transformers service lifetime loss evaluation method regarded scheming device where its execution predominantly depended on every renewable energy power system's circumspection. Therefore, there might be significant inconsistencies when describing electrical network cost and load factors employed loss evaluation procedures. These inconsistencies are based on the unique operation objectives and financial goals allotted by each renewable energy power system and the extent of analysis involved. The constituents undertaken in the procedures include the network's load profile, rate of interest and energy tariffs, and other operational expenditures.

This work is an extension of previous work presented in [13]. The aim of the current work is to develop a new formulae for establishing the cost of various transformers and their associated losses to advance the adjudication of competing transformer bid offers, evaluation of techno-economic parameters of transformers for new DSPV projects, defer replacement and strategic planning to supersede existing units in service. The advancements include: a) a new formula for calculating the transformer price per MVA and ZAR/MVA of a wide range of transformers from 1.25 – 250MVA, (b) a new formula for calculating the associated no-load and load losses per MVA and $Watts/MVA$. The proposed loss evaluation procedure by the authors and associated annualised cost of energy, interest rate, service lifetime and the generating and non-generating state factors have been adopted from previous work presented in [13] in order to evaluate the cost of service losses and TOC of the studied transformers. The results yield an error of estimation of less than 1% and 2% for the losses and associated cost; and the TOC respectively.

2. Economic Evaluation of Transformer Service Lifetime

The service lifetime loss evaluation of transformers is a procedure employed by transformer manufactures and IPP's to account for the summation of the present cost of unit of electrical energy in kilowatt (kW) of the transformer over its intended service lifetime. The loss of electrical power in transformers are defined as the no-load loss ($P_{NL} - kW$), the load loss ($P_{LL} - kW$), and the auxiliary loss ($P_{Aux} - kW$). Therefore, when determining these transformer losses, their assessment is established on the basis of the plant's energy cost ($E_C - ZAR/kW$) and energy demand ($E_D - ZAR/kW$) constituents. The energy cost ($E_C - ZAR/kW$) is the present cost of energy unit of electrical energy in kilowatt (kW)

that will be consumed by the transformer over its service lifetime within the renewable power plant [14]. Moreover, the energy demand ($E_D - ZAR/kW$) is the present value of electrical energy in kilowatt (kW) of installing an electrical load to service the energy used by the losses [14]. Insofar, the energy and demand factors of the losses are the predominant factors in the procedure of determining the cost of the renewable power plant and energy necessary to supply the service lifetime losses of transformers.

The energy and demand constituents are properly annualised to give the total loss value (ZAR/kW) which include the sum of equivalent discounted value of unit of electrical energy in kilowatt (kW) of the transformer over its intended service lifetime. The loss evaluation procedure ensue the discounted Total Cost of Losses ($TCL - ZAR/kW$) of the transformer over its intended service lifetime. The TCL of transformers can be expressed as follows in Eq. (1) as an arithmetic sum of the cost of, the cost of no-load loss ($C_{NL} - ZAR$), the cost of load loss ($C_{LL} - ZAR$), and the cost of auxiliary loss ($C_{Aux} - ZAR$).

$$TCL = C_{NL} + C_{LL} + C_{Aux} \quad (1)$$

The rate ($F_{NL}(E_D, E_C) - ZAR/kW$) that represents the cost of unit of electrical energy in kilowatt (kW) of the transformer no-load loss over its intended service lifetime is employed as follows in Eq. (2).

$$C_{NL} = F_{NL}(E_D, E_C) \times P_{NL} \quad (2)$$

The rate ($F_{LL}(E_D, E_C) - ZAR/kW$) the represents the cost of nit of electrical energy in kilowatt (kW) of the transformer load loss over its intended service lifetime expressed is employed as follows in Eq. (3).

$$C_{LL} = F_{LL}(E_D, E_C) \times P_{LL} \quad (3)$$

The rate($F_{Aux}(E_D, E_C) - ZAR/kW$) that represents the cost of unit of electrical energy in kilowatt (kW) of the transformer auxiliary loss over its intended service lifetime is employed as follows in Eq. (4).

$$C_{Aux} = F_{Aux}(E_D, E_C) \times P_{Aux} \quad (4)$$

2.1. Transformer TOC Method

The total ownership Cost (ZAR) of transformers in therefore attained using the initial buying price ($BP - ZAR$) of the transformer and its TCL as expressed in Eq. (5) [15] – [16].

$$TOC = BP + TCL \quad (5)$$

The TOC's value is an economic estimation employed to give the IPP's and investors with the overall operational and maintenance costs of their transformer expenditure. Additionally, the TOC is a planning device that can be useable according to the following conditions.

a) Optimization of the transformer design philosophy

It is widely accepted that the transformer losses in the renewable energy power systems is relatively high [17]-[18], and

the manufactures design philosophies must be imbedded with data such as a complete harmonic spectrum to design the most optimised offers. The effect of such implementation will inescapably increase the transformer price. In any event, the TOC model fortifies the reality that reducing transformer losses with expensive and lower losses transformer would comprehensively indicate the reduction of the transformer operational, maintenance and consequently the ownership cost. The consequence of this approach will have significant energy preservation for the IPP's and put off the necessity for renewable power utility energy tariffs increase.

b) Competing transformers during a bid window

The service lifetime loss evaluation procedure and the resulting TOC allows the IPP's to appraise competing transformer manufacturer's offerings in preparing to the highest degree the excellent choice of buying transformers between competing transformers and so affirm buying of the most economical units. Employing the rates $F_{NL}(E_D, E_C)$, $F_{LL}(E_D, E_C)$ and F_{Aux} that represents the cost of a unit of electrical energy in kilowatt (kW) of the DSPV transformer losses over their intended service lifetime, the financial reward of high initial buying price but low-loss units can be easily compared with lower initial buying price and high-loss units.

c) Estimation of the transformer service lifetime

The service lifetime loss evaluation procedure give knowledge to the IPP's of the estimated and most suitable time to replace an existing transformer with more economical and lower losses. This knowledge takes into consideration the financial variability between load-growth consequences under old and new units.

3. Proposed Method for Evaluating the Transformer Price and Losses

The power rating (MVA) of DSPV transformers and replacement of units in service is undertaken instinctively on the basis of the technical or economical determination. Integrating these two aspects in the decision-making process can be even more rewarding for the IPP. In this work, new formulae for evaluating the transformer price and losses for IPPs are derived. These formulae will enable IPPs to optimally use existing units in service and establish a strategic plan to replace these units. Further, these formulae are critical when selecting a suitable power rating (S) and the most economical service losses when purchasing new transformers. In the South African renewable energy market, there are a number of circumstances concerning the acquisition and replacement of transformers, including:

- Acquisition of a new transformer for the construction of a new solar project,
- Deferred replacement of transformer until end of designed service lifetime, and
- Superseding a unit in service with a larger rating.

In any case, the service lifetime of a transformer is reliant on its rating, loading profile and related annual growth. The option for IPPs to defer the replacement of transformers can only slow down

the need for new capital investment, however, with the sacrifice of the service lifetime and higher cost of the service losses of the unit.

The derived formulae in this work are based upon empirical studies conducted on a fleet of transformers intended to be of service to various DSPV systems in South Africa that are ranging from 1.25MVA to 250MVA. The evaluation of the relationship between the transformer power rating against transformer prices, no-load losses and load losses is carried out by applying polynomial regression model.

3.1. Polynomial Regression model

Polynomial regression modelling has been chosen in this work to establish the relationship between various transformer ratings against the transformer price and the guaranteed design no-load and load losses.

$$\hat{Y} = b_0 + b_1x_1 + b_2x_2^2 + \dots + b_kx_k^k$$

here,

\hat{Y} – Transformer anticipated outcome

b_0 – Y intercept

$b_{1,2,\dots,k}$ – Regression model coefficients

$x_{1,2,\dots,k}$ – Regression model independent variables/predictor

A typical graphical representation of the polynomial regression model is shown in Figure 1.

Figure 1: Typical Polynomial regression model

Some general proposition;

- The fitted data model is more credible when built on a fleet of transformer data.
- The transformer data is not extrapolated beyond the boundaries of observed data.
- The independent variables data selected are not too large as they will trigger overflow with higher order polynomials.

3.2. Transformer Price (TP)

The transformer price is dependent on various factors including ratings, materials and technical specification supplied by the customer, materials and manufacturing labour. A polynomial

regression model using a quintic function to evaluate the cost of DSPV transformers is proposed and presented as follows in Eq. (6) below. This model is built upon a fleet of transformer price data that has been analysed using the general proposition presented in the previous subsection.

$$TP = 822069 + 371895S - 10435 \times S^2 + 139.45S^3 - 0.758S^4 + 1,39e - 3 \times S^5 \quad (6)$$

here,

TP – Transformer price in ZAR

S – Transformer rating in MVA

The rating in the studied transformers considers the highest voltage systems, top oil of 55°C, mean winding temperature of 60°C and hotspot temperature of 78°C. The relationship between the ratings the TP are demonstrated graphically as shown in Figure 2.

Figure 2: MVA vs ZAR

The percentage contribution of the various components and materials that makes up the transformer price are summarised in Table 1 below. At the present time, the manufacturing of transformers is distinguished by a large range of designs required to meet a variety of customer with distinct technical requirements. Raw material prices will have an effect on these prices, but nonetheless, the percentage contribution will be somewhat as tabulated below.

Table 1: Total transformer manufacturing cost

Item	Percentage
Bushings	3%
Tapchanger	8%
Cooling System	7%
Tank Steel	4%
Windings copper conductor	17%
Cellulose insulation	5%
Liquid insulation	4%
Transformer core	5%
Fittings and accessories	5%
Factory acceptance tests	5%
Manufacturing cost	38%

The increase in the transformer price is observed to be reliant on the rating of the transformer. Another phenomenon is observed with regards to this relationship. In Eq. (7), the ZAR/MVA function is also derived and presented as a quintic function.

$$TP_{\frac{ZAR}{MVA}} = 799349 - 53395S + 1605S^2 - 21.58S^3 + 0.101S^4 - 2e - 4S^5 \quad (7)$$

Correspondingly, the graphical representation of this relationship is presented in Figure 3 below.

Figure 3: MVA vs ZAR/MVA

It is observed the function ZAR/MVA decreases as the rating of the transformer increase and slows down at about 160MVA and above.

3.3. Transformer Losses

The service no-load and load losses vary with the rating of the transformer. In the technical evaluation of competing bid offers, the service losses are critical parameters for the IPP. The quintic regression models derived for the no-load and load losses are expressed in Eq. (8) and Eq. (9) below.

$$P_{NL} = 2714 + 337.3S + 3.43S^2 - 0.036S^3 + 6,09e - 6S^4 + 2.91e - 7S^5 \quad (8)$$

$$P_{LL} = -2302 + 7837S - 112S^2 + 1.121S^3 - 0.00567S^4 + 1,04e - 5S^5 \quad (9)$$

The relationship between the service losses and the rating is demonstrated graphically as shown in Figure 4.

Figure 4: MVA vs Watts

Correspondingly, the graphical representation of the relationship between the Watts/MVA and the rating is as demonstrated in Figure 5 below.

Figure 5: MVA vs Watts/MVA

Finally, a set of new transformers intended for a DSPV project are studied in the next section to substantiate the new formulae.

4. Case Scenarios

In order to demonstrate the validity of the proposed method in this work, realistic techno-economic offers of various transformers have been provided subsequent to a request to bid issued by various IPPs within South Africa is presented in Table 2 below. The financial particulars considered in this case scenarios are adopted from our previous work [13].

Table 2: Bid offers

S	TP	P_{NL}	P_{LL}
10	3 729 213	6 437	65 506
20	4 864 152	10 541	117 661
40	6 332 296	19 533	189 746
160	13 468 698	32 230	349 712

In the next sub-section, the assessment of these offers is carried out for the individual sizes.

4.1. Application and Validation of Proposed Method

To facilitate a bona fide comparison of the proposed (prop) no-load and load loss formulae against supplied data in Table 2, Eq. (8) and Eq. (9) are applied to estimate these losses as indicated in Table 3.

Table 3: Benchmarking of no-load and load losses

S	$P_{NL(Act)}$	$P_{NL(Prop)}$	Error	$P_{LL(Act)}$	$P_{LL(Prop)}$	Error
10	6437	6394	0,67	65506	65916	0,63
20	10541	10546	0,05	117661	117667	0,00
40	19533	19441	0,47	189746	190020	0,14
160	32230	32229	0,00	349712	349714	0,00

The results indicate that the new formulae have an error of estimation of less than 1% in all cases. The proposed loss

evaluation procedure by the authors and associated annualised cost of energy, interest rate, service lifetime and the generating and non-generating state factors have been adopted from a previous work [13] in order to evaluate the cost of service losses and TOC of the studied transformers. The TOC of the units based upon the actual values is evaluated and tabulated as shown in Table 4 below. In our previous work [13], we have derived harmonic loss factors of DSPV transformers in which IPPs can apply to evaluate the cost of C_{NL} and C_{LL} as shown below. Additionally, the TOC is evaluated using Eq. (5) as expressed in section sub-section 2.1 above. Hence, Table 4 tabulates the calculated TOC of individual transformer sizes described in Table 2.

Table 4: Assessment of bid offers (Actual)

S	C_{NL}	C_{LL}	TOC
10	222 697	1 389 795	5 341 705
20	364 680	2 496 331	7 725 164
40	675 771	4 024 987	11 033 054
160	1 115 040	7 419 596	22 003 334

On the other hand, the TOC of the units based upon the new formulae is evaluated and tabulated as shown in Table 5 below.

Table 5: Assessment of bid offers (Proposed)

S	C_{NL}	C_{LL}	TOC
10	221 209	1 389 795	5 340 217
20	364 853	2 496 331	7 725 337
40	499 606	4 025 709	10 857 610
160	1 115 006	7 419 638	22 003 342

The error of estimation for Table 4 and Table 5 above is tabulated as shown in Table 6 below.

Table 6: Assessment of bid offers (Comparison)

S	C_{NL}	C_{LL}	TOC
10	0,67%	0,00%	0,03%
20	0,05%	0,00%	0,00%
40	1,37%	0,02%	1,59%
160	0,00%	0,00%	0,00%

The results yield an error of estimation of less than 2% in all of the studied transformer ranges. It is recommendable that IPPs use the new formulae in this work when planning to deploy new solar projects to indicate the cost of the units, losses, cost of operation, and the TOC.

5. Conclusion

It is well documented that the prevailing factors in evaluating the service lifetime cost of DSPV transformers are the power rating and the associated service losses. These components need to be adjusted when major considerations such as rates of exchange for materials – provided that they affect the overall acquisition of materials and manufacturing cost.

More particularly, this work defines new formulae to determine the techno-economic parameters of DPSV transformers within the South African renewable energy market by deriving the contribution of the transformer price and the service losses to the TOC. In previous work, a method to evaluate the TOC was

proposed. This method and associated price indexes are applied in the current work to determine the cost of no-load, load loss and Total Ownership Cost of various transformers. The results yield an error of estimation of 2% against actual values for all the studied costs.

Future work will explore the development of regression models for evaluating the cost of losses and the TOC.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Compared to other types of autonomous vehicles, the single-seat is the simplest when designing, since its compact design makes it an option that can simplify different mechanical aspects and enhance those of greater importance such as the steering and the braking system. Likewise, the electronic and electrical design may be a great improvement on the vehicle. It enhances the safety on road by interacting with the mechanical parts of the vehicle and increasing the driver's perspective or reaction in a larger range of scenarios. For an electric vehicle is also important to clarify that, as an internal combustion engine vehicle, it needs to be regulated and have all the necessary equipment to circulate on the streets. Other interesting information is that an electric vehicle can be recharged with electricity and it can come from renewable energy, diminishing its already lower carbon footprint. Therefore, to achieve autonomy over the detection and evasion of objects, the application of intelligent algorithms is dispensable. To achieve the obtained result, a Q-Learning algorithm was applied on the complete 3D model of the vehicle in a simulation environment, which allows finding the best parameters of forward and turning speed. In this way, by reaching a design that meets the requirements and applying the results obtained in the aforementioned algorithm, it allows their interaction in a real environment to be satisfactory.

1. Introduction

This work is an extension based originally on the groundwork presented in the 4th IEEE Sciences and Humanities International Research Conference (SHIRCON-2019) [1]. This paper will focus on the improvements of the mechanical, electronic and electrical design, as well as the implementation of the Q-Learning algorithm while Ref. [1] focuses on the preliminary design of the vehicle, the development of the vision algorithms to be used and the development structure in the simulation environment.

Obstacle detection and avoidance in autonomous vehicles is mandatory for these smart systems to work fully. To the present, there are multiple algorithms of imminent detection and evasion developed by the automotive industry with a really appreciable rate of precision. Thus, in order to get closer to achieving these results, it is essential that the mechanical, electronic and electrical design of the vehicle has specific criteria in the most important considerations that are related to the objective of detection and evasion. That is why, for example, the design of the steering

system must provide the closest modeling to reality, in order to obtain the best parameters to include in the simulation environment. On the other hand, for the overall vehicle design to respond according to the results obtained in the simulation, the electronic and electrical design must take into account the appropriate selection of components, as well as their interaction.

Consequently, Figure 1 shows the final design of the vehicle. Despite the changes made, the safety factor has maintained its value of 1.8, this is because when considering the improvements, the distribution of mass which allowed the most critical areas to be subjected to less stress.

For the additional calculus in the present paper, the approximate value of power of the vehicle is 1911 watts. The mechanical efficiency is 96%, effective power of approximately 2000 watts is required. According to the previously obtained value of power, a 2.5 HP PCM motor was selected for the impulse of the vehicle, this motor has a maximum speed of 2800 RPM. Additionally, another motor appointed to control the car's steering

<https://dx.doi.org/10.25046/aj060253>

system was required. For this case, a 350 watts DC motor was selected.

Figure 1: Isometric view of the 3D model of the chassis and components.

With the details described above, they allowed the previous research to obtain a preliminary mechanical, electronic and electrical design based on the considerations of making a low-cost prototype. Likewise, the baselines for the recognition of the environment that will allow the artificial intelligence algorithm to be trained. However, the design in general had not been developed in depth and in detail on the most relevant considerations for the intelligent algorithm, such as the vehicle's turning design and the brake system, as well as its integration into the electronic and electrical design.

This research has the following outline: Section 2 will introduce the improved vehicle's mechanical design. Next, the improved vehicle's electronic and electrical design is presented in Section 3. Then, Section 4 will present the Q-Learning algorithm results. Finally, Section 5 will discuss the conclusion of the findings.

Figure 2: Ackerman Principle [2]

2. Mechanical Design Enhancement

2.1. Steering System

The direction of a vehicle is responsible for orienting some or all of its wheels so that it takes the desired path. It was found that

for a better turning behavior, in the case of a four-wheel vehicle with its steering system on the front axle, it is necessary for the inner wheel to turn a greater angle than the outer one, because the inner wheel follows a smaller turning radius than the outer wheel. It was also found that to experience even better turning behavior, the projections of the axes perpendicular to the steering axle of the wheels must intersect at the same point. This behavior is called the Ackerman principle, after Rudolph Ackerman patented it in 1817 for use in horse carts [2]. The Ackerman Principle is shown in the following figure.

To guarantee a close point of rotation of both wheels, which ensures almost zero skid angles at low speeds when the vehicle goes around a curve, the Ackerman configuration shown in by the following expression.

$$\cot(\delta_i) - \cot(\delta_o) = w/l \quad (1)$$

Where δ_o is the steering angle of the outer wheel, δ_i is the steering angle of the inner wheel, w is the distance between the axes of the wheels, called Track, and l is the distance between the front and rear axles of the vehicle, called Wheelbase, as shown in the figure [2].

In the same way, an expression can be obtained that describes the radius of gyration of the center of mass of the vehicle in steady state. This is calculated by the following expression.

$$R^2 = a_2^2 + l^2 \cot^2(\delta) \quad (2)$$

Where a_2 is the distance on the vehicle's axis of travel between the rear axle and the center of mass and δ is the cotangent average of the internal and external angles of the wheels.

Therefore, to determine the closeness of a mechanism to the behavior of the Ackerman configuration, an error function must be determined, in this manner by minimizing its value, get the closest expected result according to the configuration that was found. This function can be expressed as a mean square error (RMS) value. In this case, the error function cannot be explicitly defined and must be evaluated for n values of the mentioned angles. The expression that determines the mean square error value of a set of discrete values of er is defined by the following equation [3].

$$er^2 = \int_{\delta_{i1}}^{\delta_{i2}} (\delta D_o - \delta A_o)^2 d\delta_i \quad (3)$$

Where δD_o is the angle of the external wheel of the developed mechanism and δA_o is the angle of the external wheel of the Ackerman configuration according to the characteristics of the vehicle for a range of internal wheel angles δ_i determined.

The drawback in this case is to be able to determine the external wheel angle δ_o for an internal wheel angle value δ_i in a given mechanism. Showers and Lee present in their document "Design of the Steering System of an SELU Mini Baja Car" a methodology to determine internal and external wheel angles for a steering mechanism used corresponding to that of a Daewoo Damas model car [4].

Finally, according to the proposed mechanical design, there is a value of w equal to 0.994 meters and a value of l equal to 1.960

meters, as well as a value of a_2 approximately 0.784 meters, for which when performing the iterations in MATLAB, it was obtained that the radius of gyration R corresponds to a value of 0.803 meters, which is within the established limits.

2.2. Braking System

The principle of a braking system is the reduction of kinetic and potential energy that a vehicle presents when it is in motion. This energy is transformed into heat energy and is dissipated in the brake discs, produced by the friction of the brake pads. Therefore, to select a component that meets the vehicle's requirements, it is necessary to find the maximum torque provided [5]. A figure illustrating this is shown below.

Figure 3: Brake Disc Diagram [5]

where F_c is the clamping force of the brake mechanism and r_e is the effective radius. The braking torque is calculated by the following expression.

$$T = 2(F_c)(r_e)(u) \quad (4)$$

According to the selected braking system, there is a value of F_c equal to 1000 Newton and a value of r_e equal to 0.09 meters, as well as a value of u , coefficient of friction, approximately 0.2, with these values it was obtained that the braking torque T corresponds to a value of 36 Newton-meters. On the other hand, the maximum torque generated by the vehicle's engine is equivalent to a value of around 32 Newton-meters. This value is the result of the chain drive reduction used; the ratio of 15 teeth on the pinion and 72 teeth on the spur gear, delivers 1:4.8, which equates to a maximum speed of approximately 583 RPM. Therefore, this torque value is less than the brake system torque.

3. Electronic and Electrical Design Enhancement

The electronic and electrical enhancement of this electric vehicle (EV) is focused in two main critical points. First, safety features like anti-lock brake system (ABS) and traction control system (TCS) were added. Second, mandatory equipment like head lights, direction indicator lights and others were considered in the design. In addition, electronic controls and better understanding of the connections are reviewed.

3.1. Anti-lock Brake System and Traction Control System

The simplest anti-lock brake and traction control systems are based on the information acquired through speed sensors that are

placed in each wheel. Both of them may use this information to control and stabilize the vehicle by assuring that the wheels are spinning as intended.

The ABS prevents the brakes from locking up the wheels. It maintains the steerability and controllability of the vehicle under braking circumstances [6]. The electronic control unit (ECU) receives the information of the speed sensors and performs control techniques in order to regulate the brake pressure applied on the pedal. Figure 4 shows a common ABS control loop of an internal combustion engine (ICE) vehicle.

The TCS prevents the wheels from overspinning. It maintains the stability and traction when accelerating [7]. In this case, the ECU receives the same information as the ABS, but, depending on the design, TCS may have two variants. On one hand, the TCS with brake intervention activates the brakes of the overspinning wheels until they match the speed of the other ones. On the other hand, the TCS with engine intervention reduces the amount of power the overspinning wheels are receiving until they match the speed of the other ones. A comparison is shown in Figure 5.

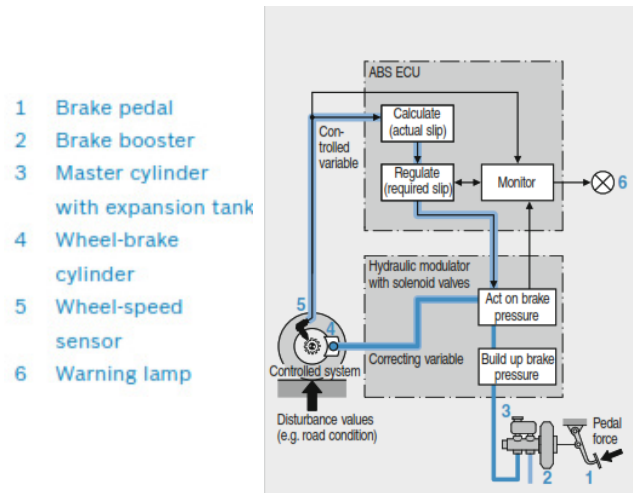

Figure 4: ABS control loop [7]

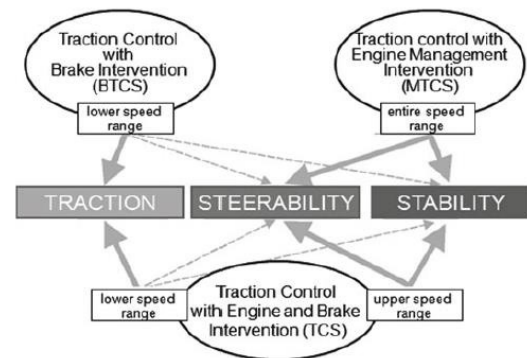

Figure 5: TCS variants comparisons [8]

These systems are tested in different types of environments and scenarios. For example, a vehicle equipped with ABS and TCS must not lose control on certain types of surfaces (e.g. wet surface), must be stable during acceleration or braking and must deal with curves without losing traction. Apart from that, it is important to know that these systems should be calibrated according to the vehicle itself because parameters like the torque of the motor or

the size of the wheels may change its dynamics, thus the control algorithm for these systems.

For this work, ABS and TCS with engine intervention are included in the vehicle's design as safety features. They are meant to be simple, effective and complementary. The objective is to increase the variety of environments and scenarios the vehicle is capable to deal with.

The connection diagram of the EV is presented to have a better understanding of the vehicle's internal distribution (see Figure 6). The main components are the 2000 watts' permanent magnet synchronous motor (PMSM), the motor controller, the 72 V lead-acid battery pack, the gear shift lever, the ignition key, the brake and the throttle. These components are enough to make the EV move forward or backward. In addition, two DC-DC converters are necessary. On one hand, a 72 V to 12 V converter is used to power other components that run on 12 V and later on 5 V for the microcontroller or sensors. On the other hand, a 72 V to 24 V converter is used to power the steering motor.

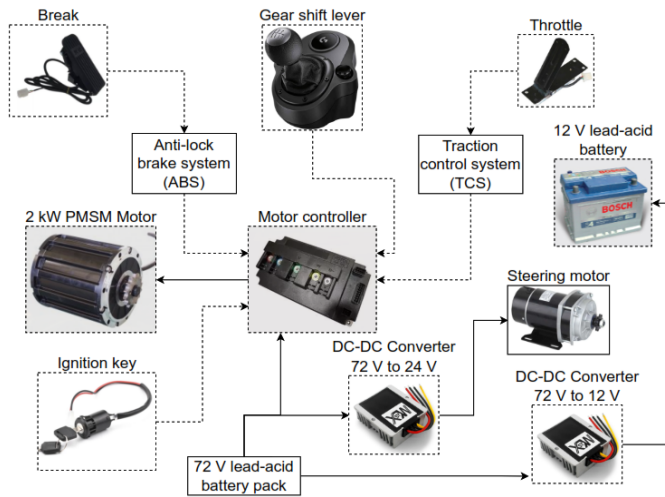

Figure 6: EV connection diagram

The throttle and the brake are different from each other. On one hand, the throttle uses hall sensors to measure its position. It is powered with 5V and delivers a signal from 1 V to 4.8 V into the throttle pin of the motor controller when manipulated. On the other hand, the brake is a simple switch that connects 12 V to the brake pin of the motor controller (electric brake). The ABS and TCS concept for this design relies on activating or deactivating the throttle and the brake when necessary. For this purpose, a window comparator circuit is implemented in Arduino and simulated in Proteus (see Figure 7).

The main components used for the simulation are the Arduino MEGA with ATmega 2560 microcontroller, the IRF9530 MOSFET transistor and the 2N3904 BJT transistor. The input signals are attached to the interrupt pins (18, 19 and 20) of the microcontroller so it doesn't miss any data while sensing. These signals simulate the speed sensors (Hall effect sensors). LED D1 and LED D2 represent the throttle and the brake (ON state means enabled and OFF state means disabled). It is important to notice that the ABS and TCS can be activated or deactivated depending on the user's decision. The user only needs to close the switch to bypass any of those systems.

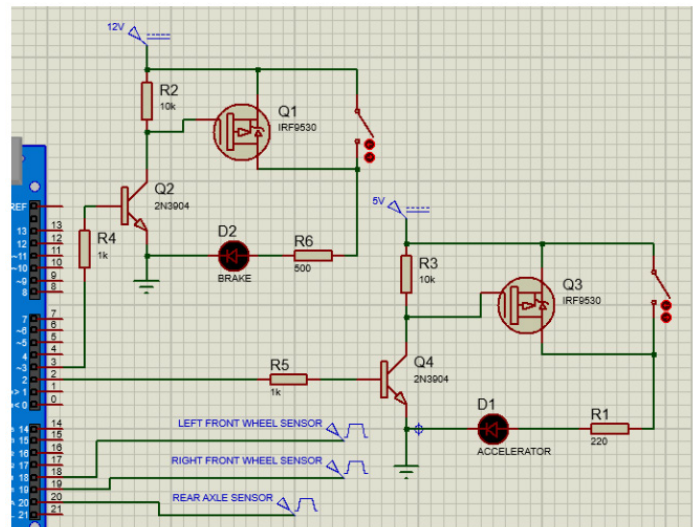

Figure 7: ABS and TCS simulation

The speed sensor used for the design is the A1104 Hall effect sensor (see Figure 8). Two are placed in the front wheels and one is placed on the rear axle. This sensor will commute when detecting the south pole of the magnetic ring (48 north poles and 48 south poles) attached to the rotary axes of each wheel. The time is measured between each pulse and compared with each sensor to determine if the wheels are locked up or overspinning. First, if the wheels lock up while braking, the microcontroller deactivates the brake (ABS) but keeps the throttle activated. Second, if the wheels start overspinning, the throttle is deactivated (TCS) but keeps the brake activated. Third, if the speed of each wheel is almost equal, no control is applied and both remain activated. A difference threshold is considered for the simulation in case the sensors do not match properly. For TCS a threshold of 5 RPM to 10 RPM was estimated and for ABS a threshold of 30 RPM or higher was considered. These values may vary depending on the road conditions and the level of the systems' effectiveness. They must be calibrated based on that information.

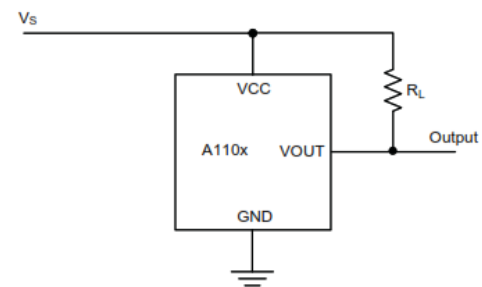

Figure 8: Schematic of the A1104 sensor [9]

The following calculations were made to assure a correct behavior of the device. The A1104 sensor has a slew rate of 2.5 V/us and it works on 5 V. This gives a 2 us rise and fall time for this voltage. It means that the signal could have a period four times the rise time, in other words, a frequency of 125 kHz before it gets distorted. The maximum speed of the motor reaches 5000 RPM (84 Hz) without load and with flux weakening. As mentioned before, there are 48 south poles that will trigger the sensor and gives a maximum frequency of 4032 Hz. This frequency is far

below the 125 kHz and determines that will work properly. The complete connection diagram is showed in Figure 9.

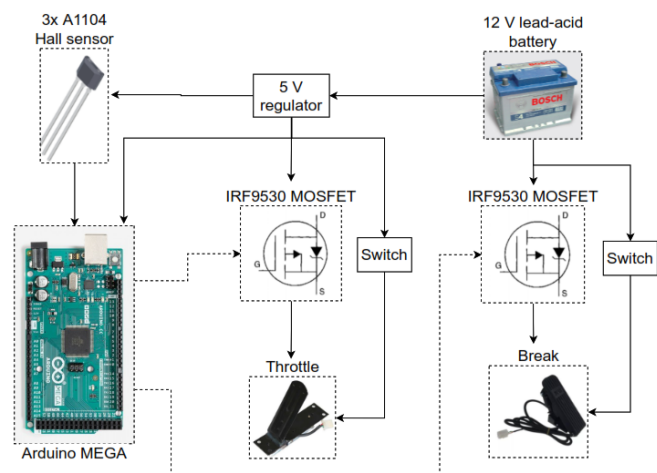

Figure 9: ABS and TCS connection diagram

Figure 10: Normal state

The results can be seen in Figure 10, Figure 11 and Figure 12 (Proteus' oscilloscope). The yellow signal represents the left front wheel sensor (only using one as a reference), the blue signal represents the rear axle sensor, the red signal controls the activation of the break and the green signal controls the activation of the throttle. First, Figure 10 shows a normal state in which both sensors match the same frequency. This means that the wheels are spinning at the same speed and no control is applied. The break and the throttle are activated (4.90 V and 4.90 V respectively). Second, Figure 11 shows an overspinning situation in which the rear axle sensor is measuring a higher frequency than the front wheel sensor. This means that the rear wheels are spinning faster than the front wheels. The brake remains activated and the throttle is deactivated (4.90 V and 0 V respectively). Third, Figure 12 shows a lock up situation in which the rear axle sensor is measuring a lower frequency than the front wheel sensor. This means that the rear wheels are spinning slower than the front wheels. The brake

is deactivated and the throttle remains activated (0 V and 4.90 V respectively).

Figure 11: Overspinning situation

Figure 12: Lock up situation

3.2. Equipment

All vehicles are enforced to follow certain specifications in their design to be admitted to circulate on the streets. Minimum requirements include head, reverse, indicator and brake lights. These lights were included in the design and are graded to be used on almost any vehicle (see Figure 13). White reverse lights are activated with the gear shift lever, red brake lights are activated if the head lights switch is closed or the brake is applied, and amber indicator lights, head lights and the cabin light are activated with a switch.

This vehicle is powered by six 12 V lead-acid batteries connected in series (total of 72 V) and a 12 V lead-acid battery for

the electronics, accessories and other equipment. Each battery has 55 Ah of capacity and the total energy of the vehicle is estimated to be 330 Ah or 4 kWh (including the six pack only). Eventually, the batteries will lose energy when being used and will need to be recharged. In this case, a commercial 72 V charger and a solar charging system is being included in the design (see Figure 14).

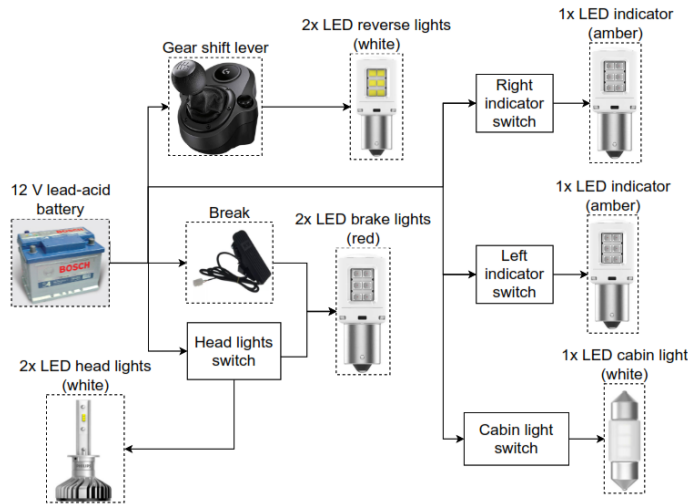

Figure 13: Lights connection diagram

The charger itself is capable of delivering 12 A, so it will take approximately 30 hours to completely charge the vehicle. It is recommended not to discharge these batteries below 40% of their capacity because they could be damaged and decrease their performance.

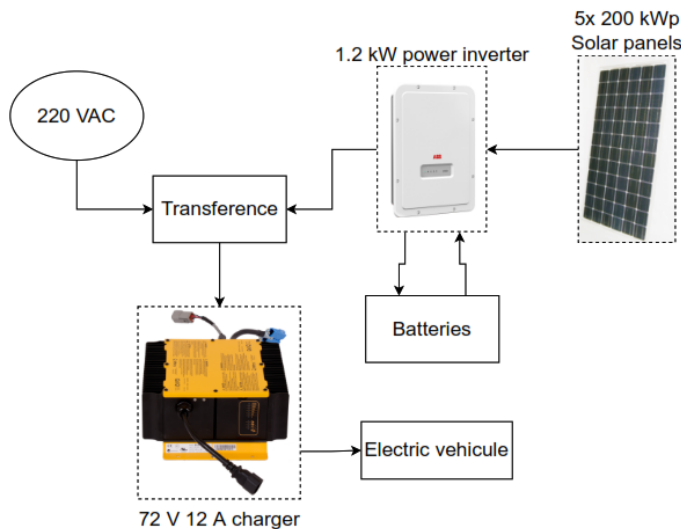

Figure 14: Charging infrastructure

The solar charging system is calculated based on a full charge for the EV assuming that it won't be discharged below 40% ($4 \text{ kWh} \times 0.6 = 2.4 \text{ kWh}$). All the parameters for this system are obtained with the software Stringsizer from ABB and it will be considered On the grid (Lima, Peru). The peak sun hour (PSH) is determined considering the mean during a year in Lima and is equal to 5.71 kWh/m^2 . The performance ratio (PR) is a constant value applied to give a margin in case more energy is required and is equal to 0.8. The kilo Watt-hour (kWh per day) is the amount of

energy needed, for this design, it is considered to be 2.4 kWh that was calculated previously. The following expression is used to establish the power needed for the solar panels.

$$kWh = (kWp)(HSP)(K) \quad (5)$$

After making the calculations, the results determine that a 0.52 kWp (kilo Watt peak) solar charging system is required. Considering a 2 m^2 and 200 Wp solar panel, the system requires a minimum of 3 solar panels. To increase the efficiency due to inverters, a group of 5 panels with a total of 1.2 kWp and a 1.2 kW power inverter are chosen. A battery bank with the same vehicle's capacity is recommended but not essential.

4. Applied Intelligence

Reinforcement learning (RL) is defined as a sequential decision-making problem of an agent that has to learn how to perform a task through trial and error interactions with an unknown environment which provides feedback in terms of numerical reward [10,11].

The Markov process is the theoretical basis of reinforcement learning, which can be expressed by the Q-learning algorithm, which is the most classical and commonly used algorithm to solve the MDP problem. It can only be used to solve MDP problems with actions and state spaces both discrete and finite. With an initial Q-table and a predefined policy, in each step, the agent selects an action based on the current state, which according to the reward is fed back and the observation of the next state, the Q table is updated using the algorithm described in the section 4.1, to finally repeat the steps until the Q function converges to an acceptable level [12].

With the Q Learning algorithm, we can allow intelligent agents to operate in environments with discrete action spaces. The discrete action space refers to actions that are well defined, such as movement from left to right, up or down.

For example, in the context of autonomous driving, while the dynamics of the autonomous vehicle is clearly a Markov decision process, the next state depends on the behavior of other elements such as vehicles, pedestrians or cyclists, which are not necessarily an MDP [13].

Therefore, in the case of the design proposed as a starting point for local research in our region, it is convenient to dispense with those elements that are not MDP. Thus, in the context of autonomous driving, given the unpredictable behavior of vehicles or pedestrians, these elements will not be considered for the reinforcement learning algorithm.

4.1. Algorithm

We start by defining the appropriate set of desires for driving based on the desired speed of the vehicle and the angle of rotation that the turn allows. On the other hand, a cost function is needed on the conduction paths that corresponds to its location by means of coordinates in a plane. The cost that is assigned to a trajectory corresponds to the weighted sum of the individual cost assigned to the speed and position. Additionally, weights are assigned to each of the costs described above to obtain a single objective function to control the trajectory. Therefore, the policy consists of a

mapping of the state of desires and a mapping of the requested trajectory. This last mapping is implemented by solving an optimization problem whose cost depends on the set of desires [14].

Algorithm 1: Q-Learning

function: Q-Learning Agent (percept) **returns** an action
 Initialization;
inputs: percept, indicating the current state s' and reward r'
persistent:
 Q , a table of action values indexed by state and action, initially zero
 Nsa , a table of frequencies for state-actions pairs, initially zero
 s, a, r , the previous state, action and reward, initially null
if Terminal? (s) **then** $Q[s, \text{none}] \leftarrow r'$
 if s is not null **then**
 Increment $Nsa[s, a]$
 $Q[s, a] \leftarrow Q[s, a] + \alpha(Nsa[s, a])(r + \gamma Q[s', a'] - Q[s, a])$
 $s, a, r \leftarrow s', \text{argmax}((Q[s', a'] - Q[s, a]), Nsa[s', a']), r'$
return a

The Q values correspond to the utility of executing each action a in state s , that is, the action of advancing or stopping in a state of object detection, as well as the action of evading by turning in a state mentioned above. Also, α and γ are the hyper parameters for tuning the algorithm.

4.2. Results

During the development of the algorithm in the GAZEBO simulation environment, it was important that the algorithm be able to calculate the "road parameters", these correspond mainly to the speed of the vehicle, which includes acceleration or deceleration, and the steering angle.

After having tried different rates of learning, no great progress has been made. This is because the optimal local solution could be due to the magnitude gap between the reward value and the punishment, leading to a large number of training epochs. on the way. Finally, the learning procedure converges after approximately 250 episodes. The vehicle can evade fixed obstacles by avoiding sudden changes in acceleration by means of a speed and angle of turn.

Figure 15: The evaluation of the algorithm

The figures below show the implementation of the model in the simulation environment together with objects that can be detected by the LIDAR sensor and the camera. Figure 16 shows how the vehicle with the sensor region and camera field of view, Figure 17 shows its interaction with the environment and Figure 18 and 19 shows the decision and evasion sequence to avoid colliding with an object.

Figure 16: Implementation of the 3D model in the simulated environment

Figure 17: Interaction of vehicle with the environment

Figure 18: Actions of the vehicle with the environment

Figure 19: Actions of the vehicle with the environment

5. Conclusions

It was achieved that the mechanical design, taking into account the manufacturing and budget limitations, is based on the methodologies for the correct operation of the system in general such as the steering system. On the other hand, design improvements will be analyzed and developed according to the completion of manufacturing. It is appropriate to mention that, as a consequence of the pandemic that has been affecting the world population, the implementation and manufacture of the vehicle has been stopped to safeguard the health of the members.

The electronic and electrical design enhancement has proved its benefits. First, safety on road has increased due to the addition of the anti-lock brake and traction control systems. The simulations determined the effectiveness of the control algorithm design for this vehicle. This algorithm was aimed to work better on wet surfaces, but it was not simulated for other kinds of terrain, like mud or gravel. It enhanced the driver response and the stability of the vehicle. Second, mandatory equipment has been added to allow the circulation of this vehicle on the streets. This also increased safety while driving among other vehicles. A future insertion to the cities automotive fleet is closer. Finally, an EV has a low carbon footprint in comparisons to the ICE vehicles. To keep this track, a solar charging system demonstrated that it is not necessary to utilize the city power, mostly if this energy is generated by hydrocarbons.

Finally, the classical Q-learning algorithm is unfeasible for more complex control problems, since each additional dimension contributes exponentially to the size of the state space, with it a significant high-dimensional preprocessing. Thus, there are other techniques such as DDPG, which combines the DQN algorithm, Deterministic Policy Gradient (DPG) and Actor-Critic [15]. The basic idea consists of the repetition of experiences to eliminate relevance, since at the moment of storing the experiences of an agent and then randomly extracting batches to train a neural network, a more solid learning for the specific tasks can be guaranteed. For example, the results obtained by Chen, Seff, Kornhauser and Xiao use the algorithm described above as a baseline, and show the penalties it gets and the large amount of processing required to reach an optimal policy (around 80,000 iterations) [16]. However, the proposal of this paper includes simplifications in the mechanical and electrical design that allow

reducing the dimensionality of the Q-learning algorithm, which results in a much faster dimensional processing and penalties close to 0 compared to the DDPG algorithm. Therefore, the best driving parameters according to the proposed vehicle design are obtained by the Q-learning algorithm. The subsequent optimization will be the training with controlled situations implemented in the simulation environment, such as street generation and route indication. In this way, once the prototype has finished its manufacture, perform the integration with ROS so that the simulation environment allows the agent to obtain the actions closest to a real situation.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

Coronavirus pandemic and transition to distance learning have significantly accelerated the introduction of Education 3.0 - 4.0 technologies into traditional educational process. This paper discusses questions of training of IT- specialists in context of Education 4.0. Based on our experience, approaches to the organization of the educational process of IT- students are considered. It is discussed, what elements of mobile learning, self-directed learning and informal learning are used by students. Informal learning in traditional educational process of IT- students is considered in such aspects as the source of knowledge, personalization, teaching/learning methods. The paper discusses a stage-by-stage approach to formation of interdisciplinary educational content for IT-students. In conclusion, the strategies of teaching / learning of Education 4.0, useful for forming of competencies for Industry 4.0, are discussed.

1. Introduction

This paper is an extension of work originally presented on the 12th International Conference on Developments in eSystems Engineering (DeSE)[1].

Pandemic changed traditional forms of educational process and accelerated introduction of e-learning technologies of Education 3.0 - 4.0. Education 3.0 is web-based, student-centered learning. Education 4.0 places the learner at the center of the educational ecosystem. Education 4.0 refers to the Industry 4.0 curricula. "The term '4.0' is related to the new technical possibilities for which the concept of E-learning or digital learning already exists"[2].

The infrastructure of Education 3.0-4.0 forms on the base of mobile technologies, social software, cloud services, online educational resources, mass open online courses (MOOC) [1]. Education 4.0 summarizes every problem that arises in 21st century education. This can be educational content, didactics, or methods [2].

Next aspects are important in advanced Training 4.0: learning on-demand, online learning in web-communities, learning

regardless of time and place, mobile learning, self-organized and self-directed learning, a combination of different training methods and environments [2].

In this paper we consider strategies of teaching/learning and formation of educational content for IT-students in the Education 4.0 concept, based on our teaching experience.

The hypothesis of the research is: in order to develop the competencies of modern specialists, it is necessary to keep in mind the experience of using modern technologies by students, regardless of teachers; on the other hand, it is necessary to develop approaches to the educational content formation and teaching/learning methods, taking into account the needs of modern industry.

Based on the survey of IT students, we shown that they independently use such the Education 4.0 technologies as mobile learning, self-directed learning and informal learning.

In conditions of the Industry 4.0 development, specialists must be ready for successful professional activities in a modern enterprise. As one of possible approaches to the educational content formation for IT students we propose the interdisciplinary

^{*}Corresponding Author: Irina Golitsyna, 35, Kremlevskaya Street, Kazan, 420008, Russia, (843) 221-34-33 & Irina.Golitsyna@gmail.com

approach based on the infocommunication infrastructure of an enterprise.

2. Literature review

The main goal of Industry 4.0 is to improve the efficiency and flexibility of enterprises so that they can adapt to the demands of the future. Technologies such as robotics, simulation, horizontal and vertical integration systems, the industrial internet of things, cybersecurity, cloud computing, additive manufacturing, augmented reality, big data and analytics can be used to achieve this goal [3]. All these technologies allow enterprises to use the vast amount of information to make more effective decisions. The development of digital technologies increases the importance of specialists who are able to interact in network environment and maintain complex production [4], [5]. In conditions of rapid development of technologies, a professional of Industry 4.0 must constantly learn from other professionals with different education and experience [3]. An important task for modern education is to identify the competencies necessary for future specialists to effectively enter the labor market [3], [6], [7]. Knowledge and competencies required for Industry 4.0 include: information technologies, software engineering, programming, data communications and computer networks, interfaces, network protocols, internet of things, systems understanding, cloud solutions, sensors and electronics, lean production. Among the competencies that new participants must have in order to implement Industry 4.0 are the following: technical skills, process understanding, understanding IT security.

Real-world experience show that the most corresponding skills and competencies are 21st century skills or competencies for lifelong learning. They contribute to the continuous and progressive self-renewing and self-regulation, and can be transferred and directly applicable in various social and professional business environments [8].

The concept of Industry 4.0 legitimizes changes in the production sphere, in the labor market, but, basically, in all spheres of society [9], including education. Education 4.0 combines various methods and approaches by which institutions of higher education align their services and curricula to prepare future graduates for work [10]. An obvious idea of universities 4.0 is: they must develop the 'learning to learn' meta-competence. This meta-competence seems to be the key to a good job and a good life; this can lead to optimization of a person and overcoming his obsolescence [11]. At the same time, Education 4.0 places more emphasis on self-directed learning using technology [12].

Education 4.0 is education for Industry 4.0, on the other hand, its infrastructure is the natural development of the infrastructure of e-learning technologies Education 1.0 - 3.0.

The formation of the Education 4.0 infrastructure leads to development of e-learning technologies as shown in Table 1 [13].

Table 1: Educational Technologies in Education 4.0

Characteristics	Education 4.0	Educational technologies
Technological platform	Mobile devices	Mobile learning.

Software	LMS (Learning Management Systems), MOOCs (Massive Open Online Courses), social software, cloud resources, professional software, open electronic platforms for online interaction	Distance learning. Educational self-organization of students in social networks.
Learning management	Collaboration of teachers and students in electronic information-educational environment (EIEE)	Flexible learning. Blended learning.
Methods of teaching/learning	Productive, in context of EIEE	Self-directed learning. Informal learning.

3. Methodology

The purpose of this study is to identify the factors contributing to the development of key competencies of IT specialists in the context of the development of Education 4.0 technologies. We consider strategies of teaching/learning in context of Education 4.0 in the next aspects:

1. Educational technologies, that develop independently of educational institutions on the basis of the Education 4.0 infrastructure, are reviewed based on literature and our experience in training of specialists of bachelor programs 09.03.02 Information systems and technologies and 09.03.03 Applied Informatics.

Quantitative descriptive research as full-time classroom survey was made to determine what elements of mobile learning, self-education and informal learning are used by students in the traditional educational process. We made a survey of students of bachelor programs 09.03.02 Information systems and technologies and 09.03.03 Applied Informatics of Kazan Federal University in 2018. In the questioning took part 96 students of 3rd and 4th years of study. From this survey we have considered such aspects, as sources of knowledge, forms of learning, self-directed learning. Questions in the questionnaire were identified and based on the literature review and the expert opinions. Our colleagues, the teachers involved in the training of IT specialists acted as experts. The survey results are presented in the form of histograms. Most of these histograms have been discussed at conferences [1], [14], or published in the paper [15]. The histograms show the ratio of positive answers on the proposed questions to the total number of respondents as a percentage.

2. We propose approach to formation of educational content for IT-students on the base of the enterprise infocommunication infrastructure. This approach has developed in our experience in training of students of bachelor programs 09.03.02 Information systems and technologies and 09.03.03 Applied Informatics in Kazan Federal University and in Kazan National Research Technical University for several years. This approach has been discussed at conferences [1], [16]. The educational content and

methodological support of disciplines within the framework of the declared approach has been published in the number of educational and methodological manuals, e.g.[17]-[19].

Feedback has come also from personal conversations with students and discussions at the alumni meetings of Kazan National Research Technical University over the years.

4. Results and Discussions

4.1. Strategies of Teaching/ Learning

We consider below, how the teaching / learning strategies outlined in Table 1, are implemented in the traditional educational process of IT professionals. We used the mentioned above survey of students of bachelor programs 09.03.02 Information systems and technologies and 09.03.03 Applied Informatics.

4.1.1. Educational Technologies of Education 4.0 in Traditional Educational Process

Mobile learning is being developed on the basis of mobile devices and technological communication channels. Immediate switch of educational institutions on distant learning stimulated to use of mobile devices in the pandemic context.

According to [20], the mobility concepts in higher education can be divided into three important directions: mobility of technology, mobility of learners and mobility of learning. Mobile devices are used by students for educational communication, for example, to discuss educational issues and exchange ideas with classmates. In general, most students think that mobile devices can help them to learn.

We can see from histogram in Figure 1 students' answers to the question: "What forms of mobile internet do you use during educational process?"

Figure 1: Students' answers to the question: "What forms of mobile Internet do you use during educational process?"

Answer options:

- [1] Search engines
- [2] Wikipedia
- [3] Cloud storage resources
- [4] Mobile access to the university library
- [5] Electronic textbooks
- [6] Social networks
- [7] Messengers
- [8] Specialized programming forums
- [9] Integrated development environments (IDE)
- [10] Mathematical problem-solving resources

www.astesj.com

Survey shows, that students actively use mobile access in the educational process to available web services, such as search engines, Wikipedia, cloud storage resources, electronic textbooks, social networks and messengers. This infrastructure of mobile learning has been developed independently of educational institutions, and teachers have been able to use the ready-made infrastructure in the educational process in the current conditions. Students use the virtual environment for access to educational resources from mobile devices, thereby using the opportunities of mobile learning.

Students form a mobile personal learning environment and become full participants in the formation of EIEE of educational institutions in accordance with the modern education development trends.

Distance learning has become an only possible form of education in the context of coronavirus pandemic. This situation accelerated the introduction of e-learning technologies into the traditional educational process. Along with LMS and MOOC, open electronic platforms for online interaction (such as Microsoft Teams, Google Zoom etc.) have been widely used in current conditions.

Flexible learning refers to the use of online learning in a traditional learning process. IT- students actively use the electronic professional environment for learning and solving assigned tasks, therefore, technology of flexible learning can be effectively used for their education. Students use web-resources in educational activities, form a personal-oriented EIEE. Teachers receive the opportunities to develop new teaching methods, to personalize learning and organize students' independent work [21].

Blended learning is developing based on the use of e-learning elements in a traditional educational process [22]. The concept of blended learning also involves learning in a workplace, which allows teachers to master and use vocational training technologies.

Self-directed learning. As noted above, self-directed learning is one of the key competencies for Industry 4.0.

We can see from histogram in Figure 2 students' answers to the question: "Are you engaged in self-directed learning?"

We can conclude, that students are independent in self-directed learning, they actively use specialized books and textbooks and programming forums, learn on educational online resources, some of them attend educational courses.

Figure 2: Students' answers to the question: "Are you engaged in self-directed learning?"

Answer options:

- [1] No
- [2] I attend educational courses
- [3] I learn on educational online resources

- [4] I use professional forums
- [5] I read specialized books and textbooks
- [6] I use programming forums
- [7] Other

Students widely use web-resources for self-directed learning and for solving academic tasks. Table 2 shows web-resources that IT-students use in various types of educational activities to form professional competencies [1].

Table 2: Learning Activities of Students with Web-resources

Learning activities	Web-resources
Educational communications of students and teachers	E-mail, social networks, cloud services
Information search	Search engines
Studying of new educational content	Electronic textbooks, educational resources, Wiki-resources
Solving mathematical tasks	Mathematical online resources, online calculators, computer algebra systems
Programming	IDE, programming forums, online professional communities

The use of web resources in traditional educational process and in self-directed learning leads to formation of personal learning environment for each student. This environment is a continuation and extension of EIEE of educational institutions, allowing teachers and students to develop teaching / learning strategies in context of requirements of Education 4.0.

4.1.2. Informal Learning

As noted above, competencies of lifelong learning are the most relevant competencies for Industry 4.0. Lifelong learning includes formal, nonformal, and informal learning. The role of informal learning has increased in current conditions. Informal learning is an unstructured learning in a family, community or/in the workplace. Mastering of informal learning experiences prepares students for lifelong learning. Development of this competence is important for professional activity of specialists in conditions of the fourth industrial revolution.

Figure 3: Students' answers to the question: "Where do you find educational content to prepare for classes?"

Answer options:

- [1] I use summary of lectures or seminars
- [2] I use an educational content recommended by a teacher

- [3] I discuss study questions with other students
- [4] I use resources of the university library
- [5] I read electronic textbooks
- [6] I use e-guides
- [7] I read articles on Wikipedia
- [8] I use specialized forums

Elements of informal learning are changing the traditional educational process of IT-students in such aspects as the source of knowledge, personalization, teaching/learning methods and teacher activities [14].

We can see from histogram in Figure 3 students' answers to the question: "Where do you find educational content to prepare for classes?" [14].

Survey shows, that students use the summaries of lectures or seminars and educational content, recommended by a teacher in educational process as often as electronic educational resources: electronic textbooks, e-guides, specialized forums. They use Wikipedia often, but only 7% of students tend to use resources of the university library.

Figure 4: Students' answers to the question: "What forms of training do you prefer?"

Answer options:

- [1] Traditional lectures and classroom workshops
- [2] Project work in a small group
- [3] Independent work outside the classroom
- [4] Solving individual tasks
- [5] Independent development of software applications
- [6] The solution of creative tasks without ready-made solutions
- [7] Other

Students give preferences to forms of training, relevant for informal learning in frames of traditional educational process. We can see from histogram in Figure 4 students' answers to the question: "What forms of training do you prefer?" [14].

Histogram shows that students prefer learning interactions (project work) in small groups and implementation of specific learning activities (independent development of software applications) rather, than traditional forms of learning. These forms of training are relevant for informal learning.

Thus, students personalize the sources of educational content, forms and methods of training, place and time of self-directed learning. Studying in formal academic groups, university students actively shape their personal learning environment and try to develop individual learning strategies.

Four factors are changing the activities of teachers: permanent changes in the subject area of education, development of sources of educational information, transformation of the educational

activities forms of students and formation of EIEE. Obviously, teachers should take into account these factors under developing of teaching strategies.

Teachers can use open educational resources for teaching and create new educational resources in collaboration with students. Web - resources and EIEE allow to restructure information in its accumulation and development, provide the ability to share and edit educational documents [1]. Use of educational and professional web-resources allows teachers to expand the content of IT disciplines, organize collaboration with students, promote the creative educational activities of students and ensure the personalization of learning.

4.2. Enterprise Infocommunication Infrastructure in Educational Content

In [23] it is proposed to combine all major engineering disciplines in the Industry 4.0 knowledge areas with their respective functions: “Designing CPS (Cyber Physical Systems), Modularity, Interoperability (Objects, machines and people need to be able to communicate through the Internet of Things and the Internet of People), Virtualization, Decentralization, Real-Time Capability, Service-Orientation”.

Kondakov distinguishes following stages of the educational content formation in the era of fourth industrial revolution [24]:

- *Pre-subject stage* includes development of general theoretical ideas about the structure and composition of educational content, taking into account prospective requests from families, society, state, peculiarities of the educational process organization in accordance with curriculum and with extracurricular activities.
- *Subject stage* includes definition of composition of academic disciplines, their content and allocation by educational levels.
- *Development of educational materials.*
- *Organization of teaching/learning strategies.*
- *Stage of assignment by students of new educational content, forms and types of activities, skills and competencies.*

Every stage is considered further based on our experience in teaching of IT-disciplines.

4.2.1. Pre-subject Stage of Formation of Educational Content

At the pre-subject stage of formation of educational content of IT-students, it should be borne in mind that modern enterprises have a permanently developing complex infocommunication infrastructure. Specialists in such infrastructure have to work in the network environment, they must be proficient in network technologies and enterprise information systems [16].

Enterprises use information technologies in different areas of their functioning: the business-processes automation, support of collaboration with partners, the electronic document flow management etc. Structure of the enterprise IT-department is built as a system of the processes managing services. This service-oriented structure allows management of IT-department to provide high quality services and efficient business solutions for an enterprise. IT-department provides services to functional

departments, and connections between them are based on the “provider - consumer” model. Functional departments set their requirements for the services of specified types and their quality. Infocommunication infrastructure is supported and developed by IT-departments according to required services and set quality. Thus the enterprise IT-department is an important resource for the enterprise management system. Table 3 shows the hierarchy of enterprise management levels and basic management functions corresponding to each level.

Table 3: Hierarchy of the Enterprise Management Levels

Level of enterprise management	Functions
Financial and economic activity	Financial planning, customer relationship, supply chain, human resources, etc.
Production activities	Operational planning, quality management, order deadlines control, productivity control, etc.
Manufacture management	Technological processes, production processes
Industrial controllers	Data collection, data processing
Sensors	Scanning of sensors, operating mechanisms

Each level performs specific management functions and uses its own computing network environment. The lowest level is sensory. At this level, a network of sensors and of various actuating mechanisms is implemented. In the context of the development of Industry 4.0, sensors will be the basis for the development of the Internet of Things [25]. The level of industrial controllers is implemented by the controller network. The industrial and office local networks are used at the manufacture management level. The local or the enterprise office networks are used at the production management levels and at the levels of financial and of economic activities of an enterprise.

The information networks have specific characteristics of functioning at every management level. The network infrastructure management must be considered during training of IT-students.

4.2.2. Subject Stage of Formation of Educational Content

At the subject stage, we offer teaching of several disciplines within the curriculum on an interdisciplinary basis as one of the educational approaches to the formation of educational content of IT- students.

A hierarchical model of enterprise architecture can be a basis for interdisciplinary connections in the professional training of IT-students. Enterprise architecture includes structured description of document flow and business processes of an enterprise, applications and automation methods that support business processes, as well as information, technology and infrastructure.

Table 4 shows levels of enterprise architecture in accordance with model TOGAF (The Open Group Architecture Framework) [17], their components and disciplines for training of IT-students.

Table 4: Disciplines for Training of IT-students in Accordance with TOGAF Model

Enterprise architecture levels	Components of enterprise information systems architecture	Disciplines for training of IT-students
Business architecture	Business applications	Information systems design. Enterprise information systems
Application architecture	Enterprise information systems	Information systems design. Enterprise information systems
Data architecture	Physical data stores, data management tools, logical and physical data models	Database. Database management systems. Enterprise information systems
Technological architecture	Infocommunication infrastructure	Infocommunication systems and networks. Network technologies. Information security

Content of studied disciplines is defined by the enterprise architecture type. Its own network computing environment with own characteristics of functioning corresponds to each hierarchical level of infrastructure. In training of IT-students, attention should be paid to the management of information network infrastructure [16].

4.2.3. Creation of Educational Materials

As noted above, knowledge related to the elements of Industry 4.0 include: networks, information technologies, interfaces and communication protocols, understanding of systems, sensors and electronics. The composition of IT disciplines can be formed in accordance with the enterprise infocommunication infrastructure. To study disciplines in which the information network environment is considered, students have to acquire next basic knowledges:

- distributed computing; distributed information-processing system;
- basic networking concepts;
- the cable and wireless technologies in local and enterprise networks; networking standards; communication interfaces;
- data communications technologies; data access, coding of signals and data;
- network services;
- life cycle management of an enterprise; service-oriented computing of business processes;
- the system development life cycle; functional subsystems of an enterprise.

4.2.4. Organization of teaching/learning strategies

An interdisciplinary approach to teaching allows organizing the following forms of learning activities of IT students:

- Creation of infrastructure of local network on real computers as practical activities. Students are invited to install the cable network, computers and communication hardware, they have to set up and test of elements of infocommunication system and network.
- Each student invited to create a virtual environment on his/her real machine to master the administration of networks. Next step is creation a virtual environment that includes a server and one (or more) networked workstations. After creating the virtual environment, the student should master the skills of configuring different network services.
- In order to master the formation and configuration of the complex services parameters, students should study the setup of terminal access, methods of organizing of the secure data transmission tunnels, the formation of help services and other issues of the enterprise infrastructure management.

4.2.5. Assignment of new educational content, forms and types of activities, skills and competencies by students

The rapid transformation of the professional environment of IT specialists requires constant updating of the content of professional disciplines. Forms and methods of teaching / learning are developing in accordance with the updating of educational content.

In our teaching activities, we constantly update the content of the taught disciplines in accordance with the development of information systems and network technologies in enterprises (e.g. [17]-[19]).

Feedback. Kazan National Research Technical University annually holds meetings of students with representatives of enterprises, and often our graduates are representatives of enterprises. Discussion of our approach to the formation of educational content and to forms of practical classes with students and alumni shows:

- the topics covered in this paper seem extremely interesting to them;
- students are interested in practical applications of technologies that they get acquainted with in classrooms;
- forms of practical classes are especially fascinating for students.

5. Conclusion

According to [6], it is too early to draw conclusions about the long-term impact of the global pandemic on education, and emergency online teaching should not be equated with pedagogically effective online teaching in accordance with the needs of students and potential employers. But it is clear, that coronavirus pandemic and rapid transition to distance learning significantly accelerated an introduction of Education 3.0 - 4.0 technologies into traditional educational process.

Development of e-learning methods takes place on this basis, and these methods are actively applied by the pedagogical community in modern situation. Introduction of e-learning technologies leads to development of EIEEE of educational

institutions and to active development of personal-oriented EIEE of students. All these aspects of advanced learning are realized by students through educational self-organization in traditional educational process.

The results of the survey of IT students presented in this paper show that they independently use such technologies of Education 4.0 as mobile learning, self-directed learning and informal learning. The survey results are consistent with our teaching experience. These processes contribute to the ‘learning to learn’ meta-competence formation and to preparation of students for lifelong learning in context of fourth industrial revolution.

Teachers need to perform the following activities in modern conditions [13]: participation in the continuous development of the EIEE of educational institution in collaboration with students; constant updating of the educational content of disciplines, which should include interdisciplinary educational content; developing teaching/learning strategies in accordance with the state of the professional environment of modern specialists.

For developing educational content in teaching IT students, we propose to use the enterprise infocommunication infrastructure as the system-forming factor. Professional activities in the conditions of permanent development of the infocommunication infrastructure of modern enterprises requires specialists to master enterprise information systems and their network environment. Teaching on an interdisciplinary basis can be considered as one of the perspective approaches to training of such specialists. Our experience shows that this approach allows to update the necessary educational content and teaching/ learning strategies in accordance with the development of the professional environment of IT professionals in modern conditions.

Table 5 shows, what possible teaching/learning strategies in context of Education 4.0 can be used for formation of competencies of Industry 4.0.

Table 5: Teaching/learning Strategies of Education 4.0 for Formation of Competencies of Industry 4.0

Competencies of Industry 4.0	Teaching/learning strategies in context of Education 4.0
Lifelong learning	Informal learning
Self-directed learning	Mobile learning. Personally-oriented EIEE of students
Programming	Informal learning. Mobile learning. Personally-oriented EIEE of students
Technical skills; information technologies; process understanding	Teaching on an interdisciplinary basis
Data communications and networks; interfaces and communication protocols; understanding of systems; understanding IT security	Teaching on an interdisciplinary basis. Enterprise infocommunication infrastructure, as the system-forming factor of educational content

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

South Africa is aiming to achieve a generation capacity of about 11.4GW through wind energy systems, which will contribute nearly 15.1% of the country's energy mix by 2030. Wind energy is one of the principal renewable energy determinations by the South African government, owing to affluent heavy winds in vast and remote coastal areas. In the design of newfangled Wind Turbine Generator Step-Up (WTGSU) transformers, all feasible measures are now being made to drive the optimal use of active components with the purpose to raise frugality and to lighten the weight of these transformers. This undertaking is allied with numerous challenges and one of them, which is particularly theoretical, is delineated by the Eddy currents. Many times the transformer manufacturer and also the buyer will be inclined to come to terms with some shortcomings triggered by Eddy currents. Still and all, it is critical to understand where Eddy currents emanate and the amount of losses and wherefore the temperature rise that may be produced in various active part components of WTGSU transformers. This is the most ideal choice to inhibit potential failure of WTGSU transformers arising from excessive heating especially under distorted harmonic load conditions. In the current work, an extension of the author's previous work, new analytical formulae for the Eddy loss computation in WTGSU transformer winding conductors have been explicitly derived, with appropriate contemplation of the fundamental and harmonic load current. These formulae allow the distribution of the skin effect and computation of the winding Eddy losses as a result of individual harmonics in the winding conductors. These results can be utilized to enhance the design of WTGSU transformers and consequently minimize the generation of hotspots in metallic structures.

1. Introduction

South Africa remains engaged in diversifying the power mix that will make it possible to reduce the subjection to coal power generation. The ongoing decommissioning of various coal power plants resulting from end of service life, can potentially make way for a radically distinct power mix as opposed to the current monopolization by coal power plants which have an installed capacity of 40GW [1]. At the present day, South Africa's Department of Energy through the Renewable Energy Independent Power Producer's Procurement Programme (REIP) has deployed a total of 64 renewable energy facilities, of which 25 are wind energy constituting of 961 wind turbines with a total generation capacity of 2,1 GW [2]. Wind energy currently contributes 52% of the country's renewable energy capacity [3]. The wind energy tariff is currently at about R0.62/kWh, in which is about 45% less

than the tariff for a coal plant. Each turbine generator in a wind energy facility is furnished with a step-up transformer at the bottom of the tower as shown in Figure 1 (a), which transforms its output voltage to a desired medium voltage (MV) collector level. In South Africa, these Wind Turbine Generator Step-Up (WTGSU) transformers are failing at an unnerving rate and utility owners are confound to ascertain the potential causes for these prevailing deficiencies. A typical WTGSU transformer failure arising from an insulation failure which is attributable to a disc-to-disc short circuit failure to generate a spark that ignites the transformer oil as shown in Figure 1 (b).

Field experience is indicating that these failures are triggered by the use of regular distribution (RD) transformers that cannot meet the required operational requirements of the wind energy environment. With the objective to pledge future dependability of wind energy in South Africa, WTGSU transformers must integrate these requirements particularly with regard to a deformed loading

cycle, harmonics and distortion, de-rating, switching over-voltages and stray gassing.

Figure 1: (a) WTGSU transformer during service; (b) Ignition of a WTGSU transformer.

Nonlinear loads and sporadic wind turbine generators are infamous for producing harmonic load currents and call for WTGSU transformers to connect them safely to the electrical network [4-5]. Transformers are commonly designed under the presumption of sinusoidal loading conditions [6-7]. It is widely known that distorted harmonic load currents accentuates the service losses in transformer and ultimately the temperature rise and generation of hotspots in metallic structures, resulting in degradation of insulation materials and untimely failures as shown in Figure 1 (b) [8-10].

Transformer windings are conceivably the most crucial part of WTGSU transformers, electrically and mechanically, and they are one of the major contribution of untimely failures in WTGSU transformers [11]. The contribution of winding conductors to WTGSU transformer failures is about 80%, which is a significant portion among the failures caused by other transformer parts [11]. In view of the increasing proclivity of nonlinear loads in the power system, the WTGSU transformers are more notably susceptible to fail. As a result, to minimize power losses and excessive heating in winding conductors, magnetic shielding [12-13], and laminating the core material [14-15] has been proposed in the literature.

At tender stage, it is essential to evaluate the transformer winding stray losses triggered by the EMFs. In this way, the inception of new formulae is recommendable and endeavor to enhance the computation and evaluation methods. A number of studies have been undertaken recently which take these objectives into account [16-20]. Thus, analytical techniques have demonstrated to be efficacious in computing the electromagnetic service losses. In a broader sense, there are two commonly used techniques in the transformer manufacturing industry to evaluate the winding Eddy current losses: (i) direct computation of the EMF

using Maxwell's equations in [21-22] and (ii) use of Poynting's theorem in [21-22]. Early attempts to compute the EMF using both these methods are presented by authors in [23]. In the book *Transformer Engineering: Design and Practice* [24], the authors described these methods and how they can be embedded into manufacturers internal design programs to compute the Eddy currents. Design programs based on the Finite element Method to compute the Eddy currents are witnessed in the publications [25-28].

Owing to the increasing renewable energy market and applications of nonlinear loads, the evaluation of the winding stray losses in WTGSU transformer necessitates the consideration of the harmonic load current spectrum (HLCS), with appropriate computation of the electromagnetic fields (EMFs). Consequently, it is essential to study the impact of the HLCS on the winding stray losses and associated temperature rise of active part components.

In the current work, an extension of the author's previous work [29], comprehensive analytical formulae to calculate the winding Eddy losses in the presence of harmonics by taking into account of the winding conductor dimensions, EMF and skin effect are derived. The acquired formulae ensure that the examination of the contribution of individual harmonics to the power losses is done. Therefore, these are effective formulae that can produce rapid results for electrical designers without the requirement of costly and high-class computational resources.

The remainder of this work is structured as follows. Section 2 outlines the challenges and electrical design considerations of WTGSU transformers. In Section 3, a winding Eddy loss formula is derived under normal operating conditions by taking into account the fundamental frequency, EMF, local flux density and winding conductor material properties. In section 4, a winding Eddy loss formula is derived under harmonic load conditions and takes into account the winding conductors, EMFs, skin effect, additionally, a new and simplified harmonic loss factor (HLF) is derived to account for the additional losses that will be seen by the WTGSU transformer during service. In Section 5, a case scenario of a WTGSU transformer supplying a distorted harmonic load is presented and corresponding losses are computed using proposed formulae. These results are then compared with the method for calculating transformer losses recommended by the IEC standard and simulation results obtained by Finite Element Method. Finally, the conclusion is presented in Section 6.

2. Electrical design concerns

A large portion of wind turbine transformers currently in service are afflicted with numerous electrical concerns. These are prevalently on account of the unpredictable wind speed round the clock during their service. These inefficacies are the main drivers of the premature failures of these transformers.

2.1. Distorted load cycle

Wind turbines depend to a large extent upon regional wind and other weather patterns, and their annual average capacity factor is close to 40% [30]. A majority of the power producers in the past projected the operational loading would be more than 50%. The comparatively light loading of WTGSU transformer present two

distinct and operationally momentous challenges that must be embedded into the design philosophy of WTGSU transformer.

The foremost challenge is that the WTGSU transformer's relatively low average capacity factor falsify purchasing adjudication and invalidate classical economic models for regular distribution transformers. On account of the ideational nature of wind energy facility developments in South Africa, the Engineering, Procurement and Construction (EPC) developer is most frequently concerned with a cheaper initial transformer price. The utility owner who takes over responsibility of the facility from the EPC take a greater interest in the Total ownership cost (TOC) of the WTGSU transformer over its designed service lifetime. These costs include the initial purchase cost of the transformer, the cost of service no-load and load losses and routine maintenance costs [31-32]. The TOC models developed by authors in [31-34] do not take into consideration the relatively low average capacity factor of WTGSU transformers. Bearing in mind that the loading cycle of WTGSU transformers is so distinct from regular distribution transformers, EPCs must be mindful of the obsolete loss capitalization formulae when evaluating the TOC for WTGSU transformers.

Another challenge is that the WTGSU transformers are susceptible to regular thermal load cycling on account of the sporadic characteristic of the wind turbines. The latter give rise to the generation of hotspots in the transformer active part components including core, windings, clamping structure, flitch plates, tank walls et cetera. Recurrent thermal stresses drives the immersion of nitrogen gas into the hot insulating oil and it is emancipated as the insulating oil cools down. This phenomena results in the production of combustible gaseous bubbles that can potentially generate partial discharges and consequently damage the cellulose insulation. Additionally, sporadic thermal cycling can expedite the aging of electrical connections within the transformer tank.

2.2. Harmonics and distortion

The transformer design principle is formed on the rationale of generating an alternating EMF from a steady sinusoidal power supply voltage to instigate the flow of current and voltage potential in the winding conductors across that EMF.

During service, a steady sinusoidal wave shape is not practical. In the power system, the voltage and current wave shapes are distorted from the theoretical sinusoidal wave shapes. In practical terms, the total harmonic distortion (THD) ranging between 1 and 2 is prevalent at the point of common coupling (PCC). The application of non-linear loads in the facility can further contribute to distortion of the voltage and current wave shapes. These accumulative distortions reiterate very cycle, embellishing peaks that mount the voltage and current wave shapes and arise at distinct frequencies from the fundamental frequency of 50 Hertz (Hz) as shown in Figure 2.

The adverse effects of harmonics is that they trigger an upsurge in the copper loss, winding Eddy loss and stray loss in other metallic components. Eddy current and circulating current generate overheating in the transformer active part components, which must be treated by a sufficient cooling system design to thermal aging and untimely failures of WTGSU transformers

during service. The wind turbine generator output, much like other renewable energy sources is intermittent and will produce distorted harmonic wave shapes. In this regard, the WTGSU transformer is operated with solid state controls which furnish additional harmonics and distortion.

Figure 2: Current wave shapes: With and without distortion

Electrical generator systems that employ electronic switching devices and circuits also present specific problems for WTGSU transformers. From a manufacturer perspective, design philosophies to minimize the Eddy current loss to redress for harmonic load currents are imperative. While harmonic filtering is particularly not a function of a WTGSU transformer, magnetic shields strategically positioned between the windings may act as filters to mitigate the distorted harmonic currents into the collector bus. As a result, magnetic shielding should be deemed compulsory in the design of WTGSU transformers.

2.3. Switching Over-Voltages

A major concern with vast, wind turbine arrays is the necessity for connecting individual WTGSU transformers to the utility collector bus, leading to lengthy runs of cables. In large-scale wind facilities with a cluster of wind turbine towers, the WTGSU transformers may be positioned near the tower base as shown in Figure 1 in order to minimize the costs of large and lengthy runs of copper cables. Problems including excessive voltage drop, cable losses and risk of ground faults may arise from lengthy cable runs.

In view of the fact that wind energy facilities are in remote areas, they are more susceptible to lightning surges. As a result, surge arrestors must be mandatory for all WTGSU transformers.

Other things being equal, the biggest concern about switching over-voltages may be that generated by the wind turbines. On a 24-hours period, depending on the intermittent nature of wind; the wind turbines may be connected and disconnected online and offline when the wind speed increase and decline respectively. The latter may also occur when circuit breakers opens and closes the WTGSU transformer from the collector bus circuit. The switching phenomena by circuit breaker operation trigger transient over-voltages into the WTGSU transformers. This occurrence is aggravated by the application of vacuum circuit breakers, which have high-speed switching times. The fusion of the transient over-voltages and capacitance of the copper cables either HV or LV WTGSU transformer side may result in stationary waves and ringing that exceed the sinusoidal voltage amplitude as shown in Figure 3.

Figure 3: Typical switching surge [35]

Excessive transient over-voltages can trigger WTGSU transformer insulation failures. The transient over-voltages as shown in Figure 3 contains fast rise-time and high voltage amplitudes which clash with the resonant frequencies on the windings and can introduce electrical stresses exceeding the dielectric capability of the windings.

3. Winding Eddy loss under normal conditions

During service the winding conductor is immersed in an alternating magnetic field and subsequently the Eddy current start to flow. The energy loss dissipated as thermal energy on account of the Eddy current bring forth the Winding Eddy losses. The phenomena in rectangular winding conductors is demonstrated in Figure 4.

Figure 4: Harmonic current profiles [36]

The derivation of the winding Eddy loss formulae is reliant on factors suchlike frequency, local flux density and the winding conductor material properties. Provided that a winding conductor has the parameters as indicated in Figure 4 namely the, length, height and thickness are denoted by L , h and τ respectively. Then the alternating magnetic flux characteristic that is perpendicular to the height and thickness can be described by the eq. (1).

$$B = B_{max} \sin \omega t \quad (1)$$

Taking into consideration a closed-path in a clock-wise direction as shown in Figure 4, of thickness dx and distance x , a presentation of a single conductor with an induced voltage in closed-path is established. The area of this closed-path is expressed as follows in Eq. (2).

$$A = 2 \times h \quad (2)$$

The amount of magnetic flux passing through the unit area in eq. (2) is expressed as follows in Eq. (3).

$$\phi = B \times A \quad (3)$$

It follows then, that the amount of magnetic flux characteristic that is perpendicular to the height and thickness in the closed-path can be described by the eq. (4).

$$\phi = B_{max} \times \sin \omega t \times 2hx \quad (4)$$

The induced voltage in the closed-path can be expressed in accordance with the Faradays law of induction as expressed in Eq. (5).

$$E = 4.44 \times f \times \phi_{max} \quad (5)$$

Equating the constant $4.44 = \sqrt{2} \pi$ yields the formula in Eq. (6)

$$E = \sqrt{2} \pi \times f \times \phi_{max} \quad (6)$$

Taking into account the amount of magnetic flux passing through the closed-path unit area the eq. (6) yields the formula expressed in Eq.(7).

$$E = \sqrt{2} \pi \times f \times B_{max} \times A \quad (7)$$

Substituting the area of the closed-path in the induced voltage formula in Eq. (7) yields eq. (8).

$$E = \sqrt{2} \pi \times f \times B_{max} \times 2hx \quad (8)$$

The resistance of the closed-path can then be expressed as follows in Eq. (9).

$$R = \rho \times \frac{(2h + 4x)}{L} dx \quad (9)$$

The winding Eddy loss in the closed-path dx is then expressed as shown in Eq. (10). Considering that the thickness of the closed-path is extremely small in relation to the height, then the distance x is negligible.

$$dp = \frac{E^2 L}{\rho \times 2h} dx \quad (10)$$

Substituting eq. (7) into eq. (10) yields the expression in Eq. (11).

$$dp = \frac{[\sqrt{2} \pi \times f \times B_{max} \times 2hx]^2 L}{\rho \times 2h} dx \quad (11)$$

Equating the constant $\sqrt{2} \pi = 4.44$ in Eq. (11) yields the formula in Eq. (12).

$$dp = \frac{[4\pi \times f \times B_{max} \times 2hx]^2 L}{\rho \times 2h} dx \quad (12)$$

Removing the square and expressing each terms to the exponent 2 yields eq. (13).

$$dp = \frac{4\pi^2 \times f^2 \times B_{max}^2 \times hL}{\rho h} \quad (13)$$

Integrating both sides of Eq. (13) and considering the closed-path then the Eddy loss can be derived using Eq. (14).

$$P_{Eddy} = 4\pi^2 \times f^2 \times B_{max}^2 \times hL \int_{x=0}^{\frac{\tau}{2}} x^2 dx \quad (14)$$

Subsequently, the solution can be expressed as follows in Eq. (15).

$$P_{Eddy} = \frac{\pi^2 \times f^2 \times B_{max}^2 \times \tau^2}{6\rho} (hL\tau) \quad (15)$$

Dividing the Eddy loss by $hL\tau$ equates to the area per unit volume as expressed in eq. (16).

$$P_{Eddy} = \frac{\pi^2 \times f^2 \times B_{max}^2 \times \tau^2}{6\rho} \quad (16)$$

Finally, the Winding Eddy loss at fundamental frequency is expressed as follows in Eq. (17).

$$P_{Eddy} = K_e f^2 B_{max}^2 t^2 \quad (17)$$

Here,

$$K_e = \frac{\pi^2}{6\rho}$$

The skin depth of penetration at fundamental frequency 50Hz may be calculated as follows in Eq. (18).

$$\delta_R = \sqrt{\frac{\rho}{\mu \times \pi \times f}} \quad (18)$$

The depth of penetration under HLC is then computed as follows in Eq. (19).

$$\delta = \frac{\delta_R}{\sqrt{h}} \quad (19)$$

In principle, the following conclusions can be drawn with regards to the Eddy current loss in relation to the area per unit volume of winding conductor based on this derivation:

- There is a direct proportion to the fundamental frequency, conductor dimension and local flux density.
- There is an inversely proportional relationship to the resistivity of the copper conductor.

4. Transformer winding Eddy loss weighting factor

4.1. Winding Eddy loss under harmonic current loading

The winding Eddy loss along a winding height (H) can be expressed as follows in Eq. (20) [37].

$$P_{winding} = P_{DC} + P_{WEC} \quad (20)$$

The standardized winding Eddy loss is then expressed by dividing eq. (18) with the rated copper loss to yield eq. (21).

$$\emptyset = B \times A \quad (21)$$

Taking into consideration that the copper loss has a directly proportional relationship with the root mean square (RMS) load current under harmonic conditions [38-40] then first part of eq. (21) yields Eq. (22).

$$\frac{P_{DC}}{P_{DC_R}} = \left(\frac{I_h}{I_R}\right)^2 = \frac{\sum_{h=1}^{h=\max} h^2 I_h^2}{I_R^2} \quad (22)$$

The contribution of the second part of Eq. (20) is as expressed in Eq. (17). The magnetic flux leakage under harmonic conditions has a directly proportional relationship to the RMS load current as expressed in Eq. (23).

$$B = K_B I \quad (23)$$

Under harmonic current conditions, the current I is expressed in Eq. (24).

$$I = \sqrt{\sum_{h=1}^{h=\max} I_h^2} \quad (24)$$

The harmonic current in Eq. (24) is expressed as I_h . As such, the Eq. (24) yields Eq. (25).

$$P_{WEC} = K \sum_{h=1}^{h=\max} h^2 I_h^2 \quad (25)$$

Here, the constant K is expressed in Eq. (17).

During service, when the transformer is operating at fundamental frequency, the equivalent rated winding Eddy loss is expressed as shown in Eq. (26).

$$P_{WEC_R} = K I_R^2 \quad (26)$$

Combining Eq. (25) and Eq. (26), the winding Eddy loss for a transformer operating under harmonic current can be expressed as shown in Eq. (27).

$$P_{WEC} = P_{WEC_R} \sum_{h=1}^{h=\max} h^2 \left(\frac{I_h}{I_R}\right)^2 \quad (27)$$

Subsequently, combining Eq. (22) and Eq. (27) yields Eq. (28). This equation is formulated on the premise that induced current is at fundamental load current I_R of the transformer during service.

$$\frac{P_{winding}}{P_{DC_R}} = \frac{\sum_{h=1}^{h=\max} h^2 I_h^2}{I_R^2} + \frac{P_{WE_R}}{P_{DC_R}} \sum_{h=1}^{h=\max} h^2 \left(\frac{I_h}{I_R}\right)^2 \quad (28)$$

Further simplification of Eq. (28) yields Eq. (29).

$$\frac{P_{winding}}{P_{DC_R}} = \frac{\sum_{h=1}^{h=\max} I_h^2}{I_R^2} \left[1 + \frac{P_{WE_R}}{P_{DC_R}} \frac{\sum_{h=1}^{h=\max} h^2 \left(\frac{I_h}{I_R} \right)^2}{\sum_{h=1}^{h=\max} I_h^2} \right] \quad (29)$$

The allowance made in order to take into account of the harmonic load current in relation to their effects on transformer thermal performance is then expressed as follows in Eq. (30).

$$F_{HL} = \frac{\sum_{h=1}^{h=\max} h^2 I_h^2}{\sum_{h=1}^{h=\max} I_h^2} = \frac{\sum_{h=1}^{h=\max} h^2 \left(\frac{I_h}{I_1} \right)^2}{\sum_{h=1}^{h=\max} \left(\frac{I_h}{I_1} \right)^2} \quad (30)$$

In principle, the following conclusions can be drawn with regards to the Eddy current loss under harmonic current loading:

- The winding Eddy loss is directly proportional to the RMS load current and the harmonic order. This relationship is similar in the computation of the stray loss in tank walls, core clamps et cetera except that the harmonic order is expressed to an exponent of 0.8 [35].
- The skin effect is not taken into consideration at high harmonic order. The magnetic flux under these conditions does not completely penetrate the surface of the winding conductors.

In the next section, a weighted loss factor that considers the skin effect is derived.

4.2. Winding Eddy loss under harmonic current loading

The Eddy current problem form part to the area of quasi-stationary electromagnetic effects of conductors. Insomuch that, the displacement current enclosed by winding conductors may incessantly be ignored in relation to the conductive current. This is indeed the case even at high frequencies given that in practice only winding conductors comprising high electric conductivity are used. Eddy currents give rise to uneven dissemination of current density in a studied cross sectional area of a conducting conductor. This inherently leads to rise in joule heating as opposed to the state produced by direct current (DC). The Eddy currents and related uneven dissemination of the magnetic flux are known as the skin effect. The rise in current density give rise to resistive heating as opposed to the DC resistance as well as a reduction in the inductance. In addressing the skin effect problem, this study adopts the Maxwell equations in [38] and remodel these equations to treat the quasi-stationary electromagnetic effects of conductors. These equations are expressed as follows in Eq. (31) and Eq. (32).

$$\text{curl } \mathbf{E} = -\mu \frac{\partial \mathbf{H}}{\partial t} \quad (31)$$

$$\text{curl } \mathbf{H} = \sigma \quad (32)$$

On the above equations an add-on of the Ohm's law as expressed in Eq. (33).

$$\sigma = \gamma E \quad (33)$$

The electric field intensity must fulfil Eq. (34).

$$\text{div } \mathbf{E} = 0 \quad (34)$$

Similarly, the magnetic field must fulfil Eq. (35).

$$\text{div } \mathbf{H} = 0 \quad (35)$$

In investigating the dissemination of current, small but sufficiently long conductors are considered. The location of the conductors in a coordinate system as demonstrated in Figure 5. The height and ratio of these conductors fulfil the condition $h \gg 2b$ and the spatial dependence on the y-coordinate may be ignored with insignificant error. When the current flows in the z-coordinate, the magnetic field has one component as described in Eq. (36).

$$\mathbf{H} = jH \quad (36)$$

In the same order, the electric field intensity has a single component as expressed in Eq. (37).

$$\mathbf{E} = kE \quad (37)$$

In the event that a winding conductor has the conductivity $\gamma [1/\Omega m]$, the permeability $\mu [1/Hm]$ and time-variant harmoniously at angular frequency $\omega [rad/s]$, by elimination the ordinary second-order differential Maxwell equations for magnetic field intensity vector is expressed as follows in Eq. (38).

$$\frac{d^2 H}{dx^2} = k^2 H \quad (38)$$

Here, the constant k is expressed as shown in Eq. (39).

$$k^2 = j\omega\gamma\mu \quad (39)$$

In investigating the skin effect in winding conductors with a spasmodic magnetic flux, the rectangular copper conductors in Figure 5 are considered.

Figure 5: Two winding conductors immersed in alternating EMFs

The spasmodic magnetic flux streams along in the z-coordinate and the interaction of winding conductor 1 and 3 with respect to

winding conductor 2 is investigated in terms of the winding Eddy loss under harmonic conditions. The effect of the remainder of winding conductors will be disregarded in order to presume that the impact of winding conductor 1 and 3 will be completely offset in the center winding conductor. Presupposing a harmonic time response of the 2nd order differential equation in Eq. (38), with the initial conditions necessitated for symmetry along the edges of the winding conductors shall be valid the equation $H_{(x=b)} = H_{(x=-b)}$ and will yield the solutions in Eq. (40) and Eq. (41) as expressed below. It is evident that the solution in this case scenario is of $h \gg 2b$ nature.

$$H_0 = H_1 e^{kb} + H_2 e^{-kb} \quad (40)$$

$$H_0 = H_1 e^{-kb} + H_2 e^{kb} \quad (41)$$

Here, H_0 is the root mean square (RMS) magnetic field strength. Additionally, the condition of $x = \pm b$ is valid since the impact along the edges of the winding conductors $= \pm h/2$ is negligible if $x = \pm b$ is satisfied. The constants of integration from Eq. (40) and Eq. (41) can then be expressed as follows in Eq. (42).

$$H_1 = H_2 = \frac{H_0}{\cosh kb} \quad (42)$$

The solution of the magnetic field strength presume the format expressed in Eq. (43).

$$H = H_0 = \frac{\cosh kx}{\cosh kb} \quad (43)$$

By association, the magnetic flux density by Eq. (42) is expressed as shown in Eq. (44).

$$B = \mu H_0 = \frac{\cosh kx}{\cosh kb} \quad (44)$$

Maxwell's 1st equation in Eq. (33), can then be expressed as follows in Eq. (45).

$$\sigma = (\text{curl} H)_y = -k H_0 \frac{\sinh kx}{\cosh kb} \quad (45)$$

The constant k is introduced into the rationalization of the equilateral hyperbola as shown in Eq. (46).

$$k = \frac{1+j}{a} \quad (46)$$

The skin depth of penetration a under harmonic conditions may be calculated as follows in Eq. (47).

$$a = \sqrt{\frac{2}{\omega \gamma \mu}} \quad (47)$$

The skin depth at various harmonic orders is demonstrated in Figure 6.

Figure 6: Depth of skin effect

The formulation of the current density is acquired and expressed as shown in Eq. (48).

$$\sigma = -\frac{1+j}{a} H_0 \frac{\sinh(1+j)x/a}{\cosh(1+j)b/a} \quad (48)$$

With the expansion of the equilateral hyperbola the modulus of the current density is expressed shown in Eq. (49).

$$|\sigma| = \frac{\sqrt{2}}{a} H_0 \sqrt{\frac{\cosh(2x/a) - \cos(2x/a)}{\cosh(2b/a) + \cos(2b/a)}} \quad (49)$$

The dissemination of the magnetic flux density and current density along the surface of the winding conductors is described by Figure 7.

Figure 7: Distribution of the magnetic flux in the cross-section of a winding conductor

The magnetic flux leakage impinging upon one conductor is expressed by Eq. (50).

$$\Phi = \int_{-b}^b h B dx = \frac{2ah\mu}{1+j} H_0 \tanh(1+j) \frac{b}{a} \quad (50)$$

The peak value of the magnetic flux leakage is given by Eq. (51).

$$\sqrt{2}|\Phi| = 2ah\mu H_0 \sqrt{\frac{\cosh(2x/a) - \cos(2x/a)}{\cosh(2b/a) + \cos(2b/a)}} \quad (51)$$

Similarly, the magnetic flux density is expressed by Eq. (52).

$$B_{max} = 2\mu H_0 \frac{a}{2b} \sqrt{\frac{\cosh(2x/a) - \cos(2x/a)}{\cosh(2b/a) + \cos(2b/a)}} \quad (52)$$

By employing Eq. (49) and introducing Eq. (52), the formulation of the current density is expressed as shown in Eq. (53).

$$\begin{aligned} \frac{1}{2\gamma b} \int_{-b}^b |\sigma|^2 dx \\ = \frac{B_{max}^2 \gamma \omega^2 b^2}{6} \frac{3}{2b/a} \frac{\sinh(2b/a) - \sin(2b/a)}{\cosh(2b/a) - \cos(2b/a)} \end{aligned} \quad (53)$$

The variable ζ is introduced here to account for expression of $2b/a$ above as shown in Eq. (54).

$$\zeta = \frac{2b}{a} \quad (54)$$

Forthwith, the Eddy loss per unit of volume of a winding conductor can be calculated using Eq. (17), where the weighted factor will be employed as expressed in Eq. (55).

$$P = \frac{B_{max}^2 \gamma \omega^2 b^2}{6} \times F(\zeta) \quad (55)$$

Here, the weighting function that takes into consideration the skin effect in winding conductors under harmonic conditions is expressed as follows in Eq. (56).

$$F_H = \frac{3}{\zeta} \times \frac{\sinh \zeta - \sin \zeta}{\cosh \zeta - \cos \zeta} \quad (56)$$

This function is presented graphically at different conductor dimensions as shown in Figure 8.

Figure 8: The function F_H and $\frac{3}{z}$

It is evident from Figure 8, that at higher harmonic order, the magnetic flux leakage does not completely penetrate upon the surface of the conductors. The latter addresses the short coming of Eq. (30).

5. Materials and Methods

In this section, a WTGSU transformer rated at 5000 KVA, 11000/33000 volts, 3-phase, 50 cycles, oil-immersed, naturally cooled (ONAN), core type, double wound with copper conductor and fitted with on load tap changer is studied. The temperature rise in oil and winding conductors is 50 °C and 55 °C respectively. The rated losses under consideration are at 75°C on normal Tap position (in Watts) as shown in Table 1.

Table 1: Rated transformer losses

Type of loss	Rated Losses (Watts)
No load	4 500
Copper	25 000
Winding Eddy	938
Other Stray	1 253
Total	31 691

The studied transformer has a full load low voltage (LV) winding current of 262,43A with a mean winding Eddy loss at the highest loss ratio under rated conditions at 15% of the Copper losses.

The load that will be seen by the studied WTGSU transformer is described as shown in Figure 9. It is preferential that this harmonic load spectrum (HLS) to which the WTGSU will be susceptible be indicated to the transformer manufacturer during bid stage. A precise evaluation for the appropriate sizing of WTGSU transformers can only be designed by estimating the particular HLS.

Figure 9: Harmonic Load Spectrum

The resultant HLFs and service losses are computed and discussed in the next section.

6. Results

6.1. Computation of Harmonic Loss Factor

It is handy to specify a single digit that may have recourse to evaluate the capability of the studied WTGSU transformer in facilitating power to the supplied harmonic spectrum above. This

value viz. the harmonic loss factor (HLF) illustrates the effective RMS heating on account of the harmonic spectrum. The calculation of the HLF is tabulated in Table 2. The HLF by FEM is computed using the procedure described in [38].

Table 2: Computation of HLFs.

h	I_h/I_1	$(I_h/I_1)^2$	IEC	Proposed	FEM
1	0,97	0,941	0,941	0,941	0,941
3	0,37	0,137	1,232	1,090	1,213
5	0,35	0,123	3,063	2,569	2,924
7	0,1	0,010	0,490	0,100	0,448
9	0,028	0,001	0,064	0,063	0,055
11	0,11	0,012	1,464	1,455	1,184
13	0,071	0,005	0,852	0,807	0,640
15	0,026	0,001	0,152	0,135	0,106
17	0,057	0,003	0,939	0,925	0,600
19	0,047	0,002	0,797	0,774	0,468
Total		1,234	9,994	8,860	8,576
$I_{rms}(p.u)$		1.111			
HLF			8,10	7,177	6,948

The ratio of the harmonic load current for each respective method and the RMS current (p.u) yields the HLFs as indicated previously.

6.2. Computation of Winding Eddy loss under harmonic current loading

The evaluation of the total service losses as a result of the HLC using the IEEE Std. C57.110-2018 is tabulated as shown in Table 3.

Table 3: Computation of total service losses: IEEE Std. C57.110-2018.

Type of loss	Rated Losses (W)	Load Losses (W)	HLF	Service Losses (W)
No load	4 500	4 500	-	4 500
Copper	25 000	30 859	-	30 859
Winding Eddy	938	1158	8,10	9 372
Other Stray	1 253	1547	1,58	2 442
Total	31 691	38 064		47 173

Under the supplied HLS, the service losses are witnessed to have a surge of about 33% and 19% from the rated and load losses respectively. The computation of the HLF for other stray loss in this work is similar to that of the winding Eddy loss as shown in Eq. (27), however these losses generated by metallic components such as tank walls, core clamp, windings, core, flitch plate et cetera are proportional to the square of the harmonic load current and the harmonic order to the exponent 0.8 as stated in [37]. The peak local load loss ratio for the HLC is computed as follows:

$$P_{LL}(p.u) = I_{rms(p.u)}^2 (1 + F_{HL} \times P_{EC-R}) \quad (57)$$

$$P_{LL}(p.u) = 1.234 \times [1 + 0.15 \times 8.1] = 1.249p.u$$

Given that the mean winding Eddy loss at the highest loss ratio under rated conditions is 15% of the Copper losses, then the load loss will be 1.15 p.u as shown below. The maximum permissible harmonic load current with the supplied harmonic spectrum is as follows:

$$I_{max}(p.u) = \sqrt{\frac{P_{LL-R}(pu)}{1 + F_{HL} \times P_{EC-R}(pu)}} \quad (58)$$

$$I_{max}(p.u) = \sqrt{\frac{1.15}{1 + 0.15 \times 8.1}} \times 262,43 = 261,048A$$

Consequently, with the supplied harmonic spectrum the studied WTGSU transformer capability is about 261.048A.

Table 4: Computation of total service losses: Proposed method

Type of loss	Rated Losses (W)	Load Losses (W)	HLF	Service Losses (W)
No load	4 500	4 500	-	4 500
Copper	25 000	30 859	-	30 859
Winding Eddy	938	1158	7,177	8 308
Other Stray	1 253	1547	1,58	2 442
Total	31 691	38 064		46 110

Under the supplied HLS, the service losses are witnessed to have a surge of about 31% and 17% from the rated and load losses respectively. The peak local load loss ratio for the HLC is computed as follows:

$$P_{LL}(p.u) = I_{rms(p.u)}^2 (1 + F_{HL} \times P_{EC-R}) \\ = 1.234 \times [1 + 0.15 \times 7.177] = 1.248p.u$$

By applying proposed method, the maximum permissible harmonic load current with the supplied harmonic spectrum is as follows:

$$I_{max}(p.u) = \sqrt{\frac{1.15}{1 + 0.15 \times 7.177}} \times 262,43 = 259,85 A$$

Consequently, with the supplied harmonic spectrum the studied WTGSU transformer capability is about 259,85A. The evaluation of the total service losses as a result of the HLC using FEM [38] is tabulated as shown in Table 5.

Table 5: Computation of total service losses: FEM

Type of loss	Rated Losses (W)	Load Losses (W)	HLF	Service Losses (W)
No load	4 500	4 500	-	4 500
Copper	25 000	30 859	-	30 859
Winding Eddy	938	1158	6,948	8 043

Other Stray	1 253	1547	1,58	2 442
Total	31 691	38 064		45 844

Under the supplied HLS, the service losses are witnessed to have a surge of about 31% and 17% from the rated and load losses respectively. The peak local load loss ratio for the HLC is computed as follows:

$$P_{LL}(p.u) = I_{rms(p.u)}^2 (1 + F_{HL} \times P_{EC_R}) \\ = 1.234 \times [1 + 0.15 \times 6,948] = 1.247 p.u$$

Based upon the FEM procedure [38], the maximum permissible harmonic load current with the supplied harmonic spectrum is as follows:

$$I_{max}(p.u) = \sqrt{\frac{1.15}{1 + 0.15 \times 6,948}} \times 262,43 \\ = 258,70 A$$

Consequently, with the supplied harmonic spectrum the studied WTGSU transformer capability is about 258,70A.

7. Conclusions

In the current work, an extension of the author's previous work [29], new analytical formulae for the Eddy loss computation in transformer winding conductors have been explicitly derived, with appropriate contemplation of the fundamental and harmonic load current. These formulae allow the distribution of the skin effect and computation of the winding Eddy losses as a result of individual harmonics in the winding conductors. The rectangular winding conductors considered are based on real transformer geometries and represents the configuration of the conductors carrying harmonic load current.

The new formulae were triumphantly corroborated by comparing their performance with computationally intensive FEM simulations, authenticating their adequacy and efficacy. On that account, our findings are handy for the transformer manufacturing industry, where the transformer anatomy and design necessitate specific performance and inexpensive computational resources.

Additionally, it has been demonstrated that the harmonic load currents minimizes the depth of skin effect, lead to an increase in the copper losses and winding stray losses and, thereby, consideration must be given for proper evaluation and design of fir for purpose transformers capable of facilitating wind power. These formulae can be applied in the transformer design systems for calculating the effects of harmonics on the transformer active part components. These results can be utilized to enhance the design of transformer s and consequently minimize the generation of hotspots in metallic structures. In this way, the developed formulae are a critical furtherance to the existing methodologies employed by manufactures.

The method herein provides a fundamental basis for subsequent development such as analysis of thermal performance of transformers in wind power technologies.

Future work involves the development of TOC model for WTGSU transformers to evaluate their economic life by considering the intermittent nature of wind turbine generators.

Conflict of Interest

The authors declare no conflict of interest.

ABSTRACT

This study is a review of the literature on open access (OA), seeking to identify trends in research on the subject. This review was conducted in the SCOPUS database and focused on the following as the main topics: 1. Financial aspects, 2. Repositories, 3. Education, 4. Academic community's perception of OA resources, 5. Tools, 6. Policies, 7. Institutions, 8. Stakeholders, and 9. Impact. Out of these topics, the financial aspect, especially in OA's publication costs, was identified as driving great interest among researchers in the field. On the other hand, the study of the impact of OA is a subject little examined. Although research on OA in the higher education sector analyzes different perspectives and describes advances, challenges, and concerns, it is fair to conclude that OA encourages the creation and dissemination of knowledge and academic communication.

1. Introduction

At present, scientific knowledge is considered a public good. Information and Communication Technologies (ICT) have not only facilitated its access, transfer, exchange, and reuse [1], but they have also generated new scenarios of control for the academic community over its production [2] in contrast to the monopoly of commercial publishers. From this point of view, open access (OA) is a mechanism and, at the same time, an international movement, whose purpose is that "any person, with an Internet connection, can freely access without economic, technical or legal restrictions to scientific, academic and cultural information" [3].

The development of this movement is supported by various declarations and initiatives such as the Budapest Open Access Initiative [4], the Bethesda Declaration on Open Access Publications [5], the Berlin Declaration on Open Access to Knowledge in Sciences and Humanities [6], the Declaration of Santo Domingo [7] and the Declaration of Salvador [8]. Thus, the implementation of OA represents both an opportunity and a great

challenge for society, particularly for Higher Education Institutions (HEIs), where it has aroused strong research interest.

It is not surprising then, that some academics have worked on the research trends observed in this field. In [9], the author present "focuses on the open-access-related conversations embedded within a serials context or OA discussions in publications targeting serials or electronic resource librarians" for the years 2008 to 2009. Likewise, in [10] the author has also tried to identify OA trends. Despite not specifically established, by exploring the bibliography of his work, it can be determined that he bases his work on documents from 1940 to 2013, although the older documents pertain to intellectual property and scientific activity. [11] "presents a conceptual literature review of the subject of open access as it is reflected in the literature relevant to digital library research", through the study of works" (published between 2010 and 2015). As it can be observed, some of these works focus on specific issues and are based on literature published before 2016. For this reason, we are interested in more recent research trends in OA in HEIs, given the central role it plays in OA, to achieve an

www.astesj.com

<https://dx.doi.org/10.25046/aj060257>

overview of the current concerns of the academic community in this field.

In the next section, the studies related to the object of study are presented followed by the methodology that guided the work carried out. Subsequently, the results and the discussion derived from the identification of the topics addressed in the OA studies are introduced prior to the conclusions.

2. Related work

OA refers to the dissemination of scientific research results, in digital format, which has undergone a peer-review process and doesn't charge subscription fees [12]. There are multiple definitions of this notion. For example, [13] bases its work on the Budapest OA Initiative, the Bethesda Declaration on Open Access Publishing, and the Berlin Declaration on OA to Knowledge in Science and Humanities, to propose "the BBB definition of OA" and summarizes the three definitions of OA as follows: "OA literature is digital, online, free of charge, and free from most copyright and licensing restrictions." For his part, in [14] is defines OA as "access online, at no cost, to peer-reviewed scientific content with limited copyright and licensing restrictions." On the other hand, Uribe-Tirado indicates that the OA is the right anyone has, without registration, subscription, or payment restrictions, to be able to read, download, copy, distribute, print, search or link the full texts or educational, scientific, or other digital content, and use them in a legitimate way according to the Creative Commons licenses assumed [12].

Furthermore, from the different definitions of OA, several issues around the OA movement have been studied. A few of these works focused on the research trends that can be observed in this field, as mentioned in section 1. In [9] the author identifies, for the years 2008 to 2009, five issues: (i) the NIH Mandates, (ii) "the increasing number of access policies adopted by universities", (iii) the "Arguments promoting OA" (par. 42), (iv) the strategies deployed to increase acceptance of OA among faculty, and (v) the roles different actors should adopt in supporting the OA movement (par. 43). The study [10] proposed four trends: "New OA publication channels" (p. 82), "legal aspects of academic publishing and OA Publishing" (p. 114), new business models around OA, and "Mandates, both institutional and from funding organizations" (p. 186). Finally, in [11] the author focusing on OA "literature relevant to digital library research" (p. 2), identifies five categories: "Open Access, Authors, Scholarly Communication, Libraries and Librarians, and Developing and Transitional Countries." (p. 2). Table 1 summarizes the trends recognized by these works, identifying the authors that distinguish each one.

Table 1: Research trends identified.

Research trends	Source
Policies and Mandates	[9,10]
Arguments promoting OA	[9]
Acceptance of OA	[9]
Actors and their roles (Authors, Librarians)	[9,11]
OA publication channels	[10]
Legal aspects of OAP	[10]
Business models around OA	[10]
Manifestations, Barriers, and Benefits of OA	[11]

Scholarly Communication	[11]
Libraries	[11]
Developing and Transitional Countries	[11]

As it can be established, there are just a few trends identified by more than one author, which is not surprising given the specificity of the focus of each work. For that reason, we are interested in analyzing current trends in research in the OA field. Although we had recently studied this subject [1], the dynamics of the field has led us to further explore if new trends in OA research in HEIs have emerged.

3. Methodology

There is an increase in research to conceptualize relevant issues and aspects of open access. For this reason, it is essential to summarize and provide an overview of these proposals. The existing literature is examined with a Systematic Mapping of Literature [15,16]. This method makes it possible to systematically and objectively identify the scope of available empirical studies to answer specific research questions. The review process has four stages: (1) Definition of research questions, (2) Search strategy, (3) Inclusion and exclusion criteria; and (4) Classification of documents (figure 1). The study stages are described below in the following subsections.

Figure 1: Methodology

3.1. Definition research questions

This study aims to identify the advances, topics, and trends of OA research and which aspects are being analyzed. Three research questions associated with the objective of the study are defined and addressed:

- What is the distribution of the publications of OA studies regarding HEIs?
- What are the topics of OA studies identified in the literature?
- What are the trends in OA considered by the studies identified in the literature?

3.2. Search Strategy

The review intends to find primary studies about OA research using a search strategy in the SCOPUS database. The search was developed through the review of the data needed to answer the research questions.

The terms "open access" and "higher education institution" were defined as keywords. These terms are connected with the conjunction "AND", yielding the search string:

$$("open\ access")\ and\ ("higher\ education\ institution") \quad (1)$$

The search was limited to the title of the study, and journal articles, excluding articles published in conferences, books, and others. The result of applying the search equation to the selected database was 871 documents. Subsequently, 11 duplicates were identified and removed.

3.3. Inclusion and exclusion criteria

We defined inclusion and exclusion criteria filters and selected relevant studies to answer the research questions.

The inclusion criteria for papers are:

- Research published between 2010 and 2020.
- Research that explicitly mentions the term open access and higher education institution in the title and abstract and present a contribution to the OA issue.
- Research in areas other than the health sciences.

The exclusion criteria of the papers applied are:

- Research focuses which is unrelated to OA.
- Duplicate studies, only the most recent is included.
- Research that is not published as peer-reviewed journal articles.

3.4. Selection and classification of studies

We identified the main articles that provided direct evidence on the research questions. The search is limited to studies published between 2010 and 2020. The initial step was to search SCOPUS, using the search equation (1).

The selection of primary studies implies three eligibility filters to select the relevant results: year of publication, full-text availability, and research of areas other than the health sciences.

Figure 2 summarizes the systematic literature review process in a diagrammatic format according to the PRISMA Statement [17], indicating the number of studies in each phase. The studies were analyzed and selected by four reviewers. Each reviewer opined on whether to approve or reject each study.

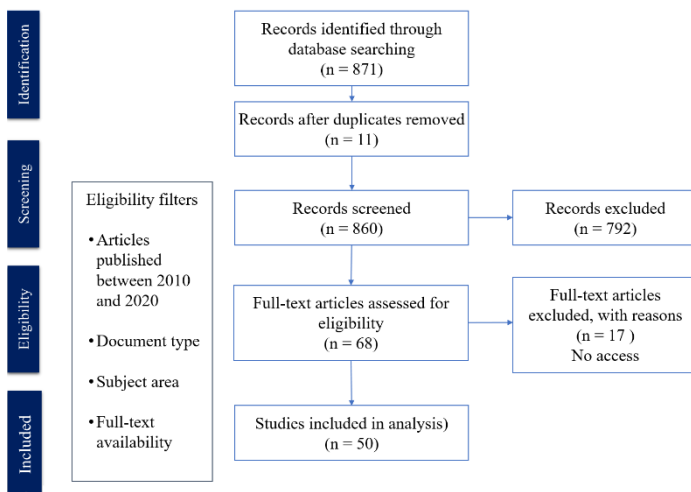

Figure 2: Number of included articles during the study selection process

As a result of the systematic literature review process, 50 primary studies were selected. These studies were organized in different categories as presented in Table 2.

Table 2: Classification according to trend

Trend	Description
Financial aspects	Aspects related to the costs and monetary difficulties linked to OA.
Repositories	Set of systems and services that facilitate the storage, management, retrieval, presentation, and reuse of digital content [18].
Education	Aspects related to the impact of OA on the teaching process of the higher education sector.
Perceptions about the use of OA resources	Surveys and interviews to consult the academic communities' opinion (students, professors, and/or researchers), about their experiences when using OA resources.
